PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain three-hundred-fifty abstracts and three-hundred-fifty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume X covers the scientific literature published from July 1971 through Dec 1972. A cumulative subject and author index for Volume X will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows.

Carcinogenesis Abstracts
Etiology Area
National Cancer Institute
National Institutes of Health
Bethesda, Maryland 20014

Use of Funds for Printing this publication
approved by the Director of the Bureau of
the Budget on July 25, 1967.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

- 5001 PRECANCEROUS STATES OF THE DIGESTIVE TRACT. (Fr.) Chevrel, B. (Hosp. St.-Antoine, Paris, France) and J.-P. Chevrel. *Vie Med* 39:4835-4844, 1971.

Data are presented on the incidence of stomach cancer occurring in the course of atrophic gastritis, Biermer's disease, hypertrophic gastritis, gastric polyposis and on incidence of cancerization of ulcers, hiatal hernias, and gastric stump following gastrectomy. In one series of 167 gastric cancers, 114 cases had concomitant atrophic gastritis. The incidence of gastric cancer in patients with Biermer's disease is three times that of stomach cancer in the general population. Of 257 patients with polyposis, 73 developed gastric cancer. Hypertrophic gastritis, characterized by chronic inflammation of the gastric mucosa, is more frequent in cancer patients than in patients with gastric or duodenal ulcers. In 167 gastric cancer cases, the mucous membrane was normal in only 31 cases. The incidence of cancerization of ulcers is between 0-20% but is difficult to evaluate because of the extent of neoplastic lesions which mask preexisting ulcers. Hiatal hernias frequently co-exist with cancer, with recent evidence suggesting that the hernia precedes the cancer. The incidence of cancer of the gastric stump following gastrectomy varies between 0.4-11%; this figure includes only cases where gastrectomy was performed to remove benign ulcers and where the cancer developed at least five yr following surgery. Methods of treating precancerous disorders of the digestive tract are indicated together with the prognosis. A hereditary predisposition is postulated in the case of Biermer's disease, atrophic gastritis, and polyposis. (No references)

- 5002 MEDICAL APPROACHES TO THE STANDARDIZATION OF CARCINOGENIC SUBSTANCES IN THE ATMOSPHERE. (Rus.) Yanysheva, N. Ya. (A.M. Marzeyev Sci. Res. Inst. Gen. Comm. Hyg., Kiev, USSR). *Gig Sanit* 37(1):90-93, 1972.

Problems of establishing standards for atmospheric carcinogens are reviewed. Such standards should be based on epidemiological data from industrial rather than from general populations; also, animal experiments are of major importance. As the determination of the harmfulness of and the significance of reactions involving carcinogenic substances is problematic, threshold values for such substances are of theoretical importance. Of the stages of the carcinogenic process prior to tumor development, the benign tumor stage is regarded as a specific indicator of the effect of carcinogenic substances. Since the conditions of atmospheric carcinogen action are by far different from those which promote skin cancer, the latter cannot be used as a criterion in atmospheric pollutant carcinogenicity evaluation. An animal lung cancer model adequate to the model of human lung cancer was obtained by intratracheal administration of hydrocarbons, which indicates the similarity of animal and human respiratory organs. Different factors facilitating the incorporation, deposition and elimination of atmospheric carcinogens in the organism (non-carcinogenic

pollutants, chemical substances increasing the solubility of carcinogenic substances, adsorbing agents and tissue and cell alterations caused by the above agents, all increasing the residence time of carcinogens in the organism) strongly influence the carcinogenic effect. Dose series, set up for the evaluation of the carcinogenic effect of the principal atmospheric hydrocarbons such as benzo(a)pyrene and benz(a)anthracene, revealed the carcinogenic effect of even small doses for large populations. Maximum allowable concentrations of carcinogenic substances in the atmosphere should be determined in animal tests, and by means of the probability theory and statistical studies of morbidity and mortality. - 5003 . MUTANTS OF ROUS SARCOMA VIRUS. (Fr.) Vigier, P. (Inst. Radium Biol., Orsay, France). *Bull Cancer (Paris)* 59(1):21-32, 1972.

The Rous sarcoma virus (RSV) is reviewed, including the nature of the viral genome, information for replication, and classes of mutants. It is postulated that its genome is replicated by DNA which directs the synthesis of RNA replicates for the production of the virus in permissive cells. The RSV carries transforming information which is apparently the same for *in vitro* and *in vivo* cells. The RSV mutants may be classified as: morphologic mutants, determining the specific structure of the transformed cells; defective mutants, either in their capacity for replication or in their power to transform cells; and conditional mutants, which include, on the one hand, mutants that have lost their transforming capacity (but not the capacity for replication) at a high temperature, and, on the other hand, mutants that have lost both capacities at a high temperature. It is suggested that the protein synthesis required for the production of the transformation, determines a modifiable alteration of the surface constituents of the cell, either in uncovering preexistent sites or in modifying their configuration or distribution. (37 references)

- 5004 ONCOGENIC VIRUSES--A REVIEW. (Ger.) Schäfer, W. (Max Planck Inst. Vir. Res. Tübingen, West Germany). *Zentralbl Bakteriol (orig)* 220:3-26, 1972.

Investigations over a 63-yr period on viral factors in oncogenesis are reviewed. Early findings demonstrating the transmissibility of chick leukemias, and even that of hen sarcomas, in filtrates were ignored for some time in favor of studies of the induction of tumors by chemical or physical means. It was only in the fifties that RNA- and DNA-containing leukemia virus tumors were described. The RNA viruses are described under the name of oncornavirus; the type of virus is designated as C- or B-particle; the hosts may be the hen, mouse, or cat; and the tumors may occur by natural infection or by induction of specific virus strains by inoculation. The DNA viruses are classified as herpes, papova and adeno viruses; the hosts include frog, hen, ape, mouse and humans (as well as other mammals). The formation of the various

viruses and their structural differences are described. In a description of the influence of tumor viruses on cells in tissue cultures, the SV40, the polyoma virus, and the C viruses are detailed. The oncogenic viruses in humans and the possibilities of immuno-prophylaxis and therapy are reviewed. (46 references)

- 5005 NEOPLASTIC ALTERATIONS OF CELLS *IN VITRO* BY CHEMICAL CARCINOGENS. (Ger.) Thust, R. (Med. Acad. Erfurt, East Germany) and T. Schramm. *Arch Geschwulstforsch* 39(3):249-263, 1972.

Studies of the mechanisms of cancer formation and investigations of cells, tissues and organ cultures for evidence of the carcinogenic properties of chemical substances are reviewed. The most important data are summarized in a table listing the chemical carcinogens tested, alterations *in vivo* or *in vitro*, the cell type, and the literature reference. On the basis of the experimental work described and observations of spontaneously altered cells, it becomes clear that morphological alteration is in no way identical with neoplastic alteration, which requires that the affected cells retain the property for the production of malignancy after transplantation to a histocompatible host. The conditions for organ cultures must be such that: the cells are not inclined to spontaneous alterations; the *in vitro* behavior is representative of the intact organism; and a variety of effects are seen in response to various carcinogens. Besides the morphologic and neoplastic alterations, the toxic effects of various carcinogens are mentioned. (48 references)

- 5006 THE ROLE OF TOBACCO IN RESPIRATORY PATHOLOGY. (Fr.) Chretien, J. (Intercommunal Hosp., Creteil, France), A. Hirsch, A. Harf and M. Thiebaut. *Rev Tuberc Pneumol (Paris)* 36(2):243-280, 1972.

Studies of chronic smokers, especially cigarette smokers, have revealed that this group presents the highest risks for bronchial cancer. The cytological characteristics of the bronchial epithelium closely associated with tobacco consumption are loss of ciliation of the epithelium, an increase in basal cells (global epithelial hyperplasia), and the appearance of nuclear anomalies. These transformations increase in intensity with increasing tobacco consumption. Experiments in animals have shown that tumors can be induced by application of tobacco condensates and that precancerous conditions in the tracheobronchial mucosa can be elicited by exposing animals to smoke inhalation. Extrapolation of such experimental results to human carcinogenesis is difficult, since the histology, anatomy, genetic factors, dosage, cofactors and other conditions are bound to differ from those of humans. Many investigators believe that the carcinogenic action of tobacco is a direct effect of aromatic polycyclic hydrocarbons and nitrosamines, but radioactive elements have also been implicated in this action. The mediator roles in the production of cancer have been attributed to enzymatic action,

immuno-depressive action, contaminants (insecticides, additives), alteration of the purification process (mucociliary clearance) and the modification in macrophages. Carcinogenic cofactors include radioactivity, in connection with certain occupations (metal industries and illuminating gas), exposure to asbestos, the urban atmosphere, viral infection, genetic or racial factors, and alcohol. The quality and mode of consumption are important considerations, although it is not clear why cigarettes are more hazardous than cigar or pipe smoking. The reduction of tar content and of specific carcinogens is currently being pursued. Repeated warnings of the harmful effects of tobacco are urged together with a campaign to discourage smoking among the young. (192 references)

- 5007 ON THE BIOCHEMISTRY OF CARCINOGENIC N-NITROSO-COMPOUNDS. (Ger.) Krliger, F.-W. (German Cancer Res. Ctr., Heidelberg, West Germany). *Aerztl Forsch* 26(6):197-202, 1972.

The carcinogenic properties of the N-nitroso-compounds are reviewed in connection with experimental cancer research. These compounds have a relatively simple structural formula and are easily synthesized. They have a marked organotropic action, as demonstrated with methylnitrosourea in the production of tumors in the central and peripheral nervous systems. They have been formed endogenously by a combination of secondary amines and nitrites. The extensive work which stemmed from Magee and Farber's application of the carcinogens to the formation of 7-methylguanine in the nucleic acids was concerned with the transference of a molecular group of a carcinogen to the genetic material. No connection between the alkylation of genetic material and carcinogenic effects could be established, although the toxic effect could be explained on a molecular basis. The possibility of a connection between carcinogenic and antineoplastic action, as seen in clinical chemotherapy, is discussed. (36 references)

- 5008 PHOSPHATE MEDIATION OF THE CRABTREE AND PASTEUR EFFECTS: DOES A CHANGE IN ENERGY METABOLISM ENHANCE THE POTENTIAL FOR MALIGNANCY? (E.) Koobs, D. H. (Loma Linda U. Sch. Med., Calif.). *Science* 178(4057):127-133, 1972.

Observations of mitochondria from cells evincing the Crabtree effect are reviewed, and the bearing of this effect on carcinogenesis is discussed. The Crabtree effect is a manifestation of respiratory inhibition in cells after the addition of glucose or another hexose capable of being phosphorylated by hexokinase. The phenomenon has been observed in malignant cells, including Ehrlich ascites cells. The Crabtree effect is usually accompanied by mitochondrial contraction and a decrease in the rate of glucose utilization occurring at the time of inhibition of respiration. Observations of the effect in mitochondria isolated from tumor cells are described. It has been

(5009-5012)

suggested that the Crabtree effect is based on competition between cells for phosphate. This, if true, might indicate that the Crabtree effect and the Pasteur effect (i.e., anaerobic glycolysis exceeds aerobic glycolysis) have the same mechanism. Both Pasteur and Crabtree effects may signalized changes in metabolic emphasis which may be associated with malignant change. (54 references)

5009 CHROMIUM AND NICKEL. (E.) Kazantzis, G. (Middlesex Hosp., London, England). *Ann Occup Hyg* 15:25-29, 1972.

Both chromium and nickel have been shown to have a limited but definite carcinogenic potential in man. Workers producing chromates and dichromates from the raw materials, chromite and chrome iron ore, have shown a 30-fold increase over the expected incidence of lung cancer. Calcium chromate has been implicated as at least one of the actively carcinogenic compounds. Although epithelial ulcerations have occurred in persons exposed to chromates or bichromates in industries where these compounds are used rather than manufactured, increased mortality from cancer has not been observed. However, no detailed epidemiological study of such workers has been performed. Nickel workers in England and South Wales were found to have a five times higher incidence of mortality from lung cancer and a 150 times higher incidence of mortality from nasal cancer than that experienced by the general male population. The mortality rates were highest among the process workers. Evidence also suggests that this risk is not experienced by workers who have only been employed in refineries modified to reduce exposure to nickel compounds. Experimental work has substantiated the carcinogenic effects of nickel. The less soluble nickel compounds show the highest carcinogenic potential while the soluble salts are nontumorigenic. Nickel carbonyl, a gaseous by-product of the refining process, has been shown to inhibit DNA-dependent RNA synthesis. Chromium compounds, in contrast to many nickel compounds, have a limited carcinogenic potential in experimental situations. (19 references)

5010 ETIOLOGY OF LUNG CANCER: REFLECTIONS ON TWO DECADES OF RESEARCH. (E.) Wynder, E. L. (Amer. Hlth. Fdn., New York, N.Y.). *Cancer* 30(5):1332-1339, 1972.

The evidence of the carcinogenicity of cigarette smoke for the human lung is reviewed and predictions concerning the future relationship between smoking and lung cancer are advanced. Evidence that cigarette smoke causes lung cancer in men includes (a) retrospective studies showing a dose-response relationship between number of cigarettes smoked and lung cancer risk; (b) the finding that lung cancer is correlated with smoking in population groups (e.g., religious groups which proscribe smoking have low lung cancer rates); (c) the fact that lung cancer risk declines among ex-smokers; and (d) the finding that identifiable carcinogens in cigarette smoke condensates cause skin tumors in laboratory animals. There is evidence that

smokers of filter cigarettes, cigarettes which are relatively low in tar, have a lower lung cancer risk than smokers of unfiltered cigarettes. It is predicted (a) that lung cancer among American white males will begin to decline due to reduced tar contents of cigarettes smoked; (b) that lung cancer will concentrate increasingly in the lower socioeconomic orders, since individuals in these strata quit smoking less frequently than those in higher strata; and (c) that tar contents of cigarettes will continue to be reduced by manufacturers, resulting in availability of decreasingly carcinogenic cigarettes. (43 references)

5011 GLYCOLYSIS, RESPIRATION, AND ANOMALOUS GENE EXPRESSION IN EXPERIMENTAL HEPATOMAS: G. H. A. CLOWES MEMORIAL LECTURE. (E.) Weinhouse, S. (Temple U. Sch. Med., Philadelphia, Pa.). *Cancer Res* 32(10):2007-2016, 1972.

Studies of the alteration of enzymes which determine metabolic processes in cancer cells are reviewed. Among the demonstrated molecular changes in Morris hepatomas are losses of enzymes which are under host regulation and which are geared to liver function (e.g., glucokinase, aldolase B). These enzymes are replaced in cancer cells by enzymes which are not under host regulation, and which are geared to the efficient utilization of metabolic fuels (e.g., hexokinase, aldolase A). It is suggested that the loss of regulatory enzymes is a key to the unbridled proliferation of cancer cells. Furthermore, progressive loss of regulatory enzymes as tumors become more undifferentiated may explain the observed increase in aerobic glycolysis in relatively anaplastic tumors. The role of genetic alterations in the changed pattern of enzyme function in tumor cells is briefly discussed. (94 references)

5012 AROMATIC AMINES: THE PRESENT STATUS OF THE PROBLEM. (E.) Veys, C. A. (British Rubber Manufacturers' Assoc., Birmingham). *Ann Occup Hyg* 15:11-15, 1972.

Data on the occupational hazards associated with aromatic amines, potent bladder carcinogens, are reviewed. The eight occupational categories in which increased bladder cancer incidence may be related to aromatic amine exposure are chemical and dyestuff industries; textile dyeing and printing; pigment manufacture; rubber and cable making; gas workers; laboratory workers; rodent control; and patent fuel, tar and pitch workers. As yet no safe exposure level has been established for aromatic amines. Two aromatic amines α -naphthylamine and β -naphthylamine are released by burning tobacco, and may cause the observed high incidence of bladder cancer in heavy cigarette smokers. Three carcinogenic aromatic amines that may present risks for laboratory and chemical workers are benzidine, *o*-tolidine and *o*-dianisidine. A report from the United States indicated an apparent excess of deaths from cancer of the pancreas and malignant lymphoma in members of

the American Chemical Society, but surprisingly few cases of urinary bladder cancer. In Britain, there has been no purposeful survey of bladder tumor incidence among aromatic amine-exposed chemical and laboratory workers. (18 references)

- 5013 PATHOGENESIS OF RADIATION-RELATED LEUKAEMIA AND LYMPHOMA: SPECULATIONS BASED PRIMARILY ON EXPERIENCE OF HIROSHIMA AND NAGASAKI. (E.) Anderson, R. E. (Atomic Bomb Casualty Comm., Hiroshima, Japan), H. Nishiyama, Y. Ii and K. Ishida. *Lancet* 7759:1060-1062, 1972.

Data on radiation induction of leukemia and lymphoma are briefly reviewed. Leukemia and lymphoma are closely related conditions but the prevalence of the two diseases in populations exposed to ionizing radiation is very different. Leukemia incidence is increased in radiologists, children exposed to diagnostic X-rays *in utero*, patients receiving radiotherapy for ankylosing spondylitis, radium workers and survivors of the bombings of Hiroshima and Nagasaki in 1945. Radiation-induced leukemia also occurs in a wide variety of laboratory animals. Increased prevalence of radiation-related lymphoma has been noted only in radiologists, Hiroshima survivors (not Nagasaki survivors) and ankylosing spondylitis patients. Moreover, mice exposed to ionizing radiation do not show increased lymphoma incidence. The difference in inducibility of leukemia and lymphoma by radiation suggests a difference in the pathogenesis of the two conditions; while leukemia may follow marrow hypoplasia, lymphoma may be more closely related to disruption of immunological homeostasis. (48 references)

- 5014 POTENTIAL CARCINOGENIC EFFECT OF CADMIUM IN ANIMALS AND MAN. (E.) Malcolm, D. (Chloride Electrical Storage Co., Ltd., Manchester, England). *Ann Occup Hyg* 15:33-36, 1972.

Previous experimental work has shown that s.c. administration of cadmium will produce malignant tumors (sarcomas) at the site of injection in male and female rats, and Leydig-cell hyperplasia and Leydig-cell tumors in male rats. Studies of British workers exposed to cadmium for 10 yr or longer revealed a significantly increased incidence of prostatic carcinoma; however, a specific survey of cadmium and/or nickel workers in other countries produced no confirmed cases of prostate carcinoma. Preliminary results from experiments in which C.B. hooded rats and Swiss mice received daily or weekly doses of cadmium sulfate either s.c. or by gastric intubation for two yr also indicate that cadmium is unlikely to be the cause of prostatic cancer or other internal cancers in man. Although Leydig cell tumors occurred, they were seen in both control and experimental animals. (15 references)

- 5015 THE ROLE OF VIRUSES IN MAMMARY CARCINOGENESIS. (Fr.) Hollmann, K. H. (Lab.

Cytopath., Broussais Hosp., Paris, France) and J. M. Verley. *Path Biol* 20(1-2):83-103, 1972.

Mouse mammary tumor viruses (MTV) are described and formation of A and B particles is illustrated. The five major polypeptides of the viruses are enumerated with their molecular weights, and a comparison is made between proteins and mouse leukemia viruses. MTV antigens and their analysis by immunofluorescence in cell cultures are described. The biological activity cycle of MTV, transmitted from the mother to her offspring by means of her milk, is outlined. The mode of absorption and primary replication *in vivo* is not known. Not all mice who receive the virus develop a mammary tumor; the oncogenic activity of the virus is conditioned by hormonal, genetic, and immunologic factors in the host. Tests for the detection of MTV are described and include the injection of noncellular extracts into newborn mice; nodulogenesis; the *in vitro* test of immunodiffusion; and the agglutination inhibition test. Replication of MTV *in vitro* is also described. Mammary tumors and leukemias are discussed in terms of relationships between B and C particles. Mammary tumors in the rat are described in terms of chemical, hormonal, and viral induction. Mammary tumors in monkeys and in humans are discussed, and the probabilities of a viral origin are argued. (272 references)

- 5016 A UNIFYING HYPOTHESIS CONCERNING THE NATURE OF MALIGNANT GROWTH. (E.) Holley, R. W. (Salk Inst., San Diego, Calif.). *Proc Nat Acad Sci USA* 69(10):2840-2841, 1972.

A theory is proposed according to which cell growth is regulated by availability in the cell of certain low molecular wt nutrients associated with cell growth. No additional "signal" to grow is needed if all these nutrients are present in sufficient concentrations within the cell. Selectivity of growth control could be achieved via transport systems at the cell surface membrane, systems which are in turn regulated by hormones or growth factors. Changes in uptake mechanisms caused by changes in the cell membrane would lead to abnormally high concentrations of critical growth nutrients inside cells, with the result that neoplastic growth is put underway. (21 references)

- 5017 RELATIONSHIP OF THE SELECTIVE METASTATIC BEHAVIOR OF TUMORS OF RETICULAR TISSUES TO THE MIGRATION PATTERN OF THEIR NORMAL CELLS OF ORIGIN. (E.) Pilgrim, H. I. (U. Utah Coll. Med., Salt Lake City). *J Nat Cancer Inst* 49(1):3-6, 1972.

Evidence supporting the hypothesis that selective metastasis of reticular tissue tumors is a vestige of the migration patterns of the tumors' normal cells of origin is briefly reviewed. According to this hypothesis, the selective metastatic preference

(5018-5022)

of tumors is a result of differential cell migration rather than of differential cell growth. For example, cells of a Hodgkin-like reticulum cell neoplasm implanted in the spleen (preferred site) tended to remain there, whereas cells implanted in the kidney (a nonpreferred site) tended to migrate out. Experiments have suggested that the tendency of lymphocytic tumors to produce leukemia is proportional to the circulating properties of the normal lymphocytic cells of origin. Evidence supporting the differential migration theory of selective metastasis has also been gathered in experiments with plasma cells and plasmacytomas, and in other work with reticulum cells and reticulum cell sarcomas. The value of transplantable reticular tumors as tools for studying the function of cells of the normal immune system is emphasized. (29 references)

- 5018 THE COMBINED EFFECTS OF SMOKING AND OCCUPATIONAL OR URBAN FACTORS IN RELATION TO LUNG CANCER. (E.) Waller, R. E. (St. Bartholomew's Hosp. Med. Coll., London, England). *Ann Occup Hyg* 15:67-71, 1972.

Studies attempting to relate lung cancer to cigarette smoking and occupational or environmental factors are reviewed. Although there is some evidence that cigarette smoking and lung cancer mortality are related to occupational factors for asbestos, uranium and nickel workers, small nonsmoking samples make these studies inconclusive. The author sees no clear evidence that air pollution, by itself or in combination with smoking, is a major factor in lung cancer development. (19 references)

- 5019 CARCINOMA RISK FACTORS IN THE DERMATOLOGY OF ACTINIC CARCINOGENESIS. (Ger.) Luger, A. (Dermatol. Div. Vienna City Hosp., Austria). *Oest Z Erforsch Bekamp Krebs* 26(6):404-417, 1971.

The effects of direct sunlight and other forms of UV light on the human skin and their relationship to cancer formation are reviewed. Animal experiments have demonstrated that skin carcinomas can develop by means of UV. In man, an acute overdose of UV evokes early symptoms of erythema in the exposed locations and these are followed by melanin synthesis. Later developments include atrophy and hyperkeratosis. UV also induces dimerization of thymidine in the chromosomes of the epithelial cells; further harm may be prevented (if the exposure was not excessive) by the "dark repair system". In the connective tissues, UV causes depolymerization of mucopolysaccharides, damaging fibroblasts and leading to an elastosis. Individual light-screening mechanisms can weaken the effects of sunlight on the skin. Some individuals are more sensitive to these effects than others, depending upon skin pigmentation. The irreparable phototraumatic microinjuries accumulate in the skin and eventually lead to clinically manifested changes. Such damage ensues when the product of concentration and time exceeds the individual tolerance threshold. This is also true for X-ray

exposure. Skin carcinoma is more apt to develop from a large number of small exposures than from one short exposure to intense irradiation. (43 references)

- 5020 APOPTOSIS: A BASIC BIOLOGICAL PHENOMENON WITH WIDE-RANGING IMPLICATIONS IN TISSUE KINETICS. (E.) Kerr, J. F. R. (Dept. Path., U. Aberdeen, Scotland), A. H. Wyllie and A. R. Currie. *Brit J Cancer* 26:239-257, 1972.

The process of apoptosis -- a general mechanism of cell deletion, complimenting mitosis -- is described and its role in normal and neoplastic tissues is discussed. Apoptosis affects scattered single cells; nuclei and cytoplasm of these cells condense, nuclei become fragmented, and cells break down into membrane-bounded, compact remnants. These remnants are taken up by other cells where they undergo changes similar to *in vitro* autolysis in phagosomes. Apoptosis has been found to occur in healthy tissues and in embryos. Focal apoptosis may play a vital role in embryonic processes. Apoptosis also occurs in teratogenesis and carcinogenesis. Apoptotic bodies (breakdown fragments of cells) have been found in human rectal adenocarcinomas and basal and squamous cell carcinomas. Apoptotic bodies have also been found in rat mammary tumors induced by 7,12-dimethylbenz(a)anthracene (DMBA). Apoptosis may also be important in therapeutically induced tumor regression. Agents that induce apoptosis include DMBA, steroid hormones, hepatotoxins and electromagnetic radiation. (51 references)

- 5021 CARCINOGENESIS IN THE CONTEXT OF OCCUPATIONAL HYGIENE. (E.) Roe, F. J. C. (Tobacco Res. Council, London, England). *Ann Occup Hyg* 15:1-7, 1972.

Factors complicating the extrapolation from animal experiments with carcinogens to human occupational hazards are discussed. Among these factors are environmental agents which may predispose men to cancer (e.g., by impairing immunological surveillance) without themselves being complete carcinogens for men or animals, and agents which modify carcinogen activity in one species but not in others (e.g., tumor promoters). In addition, agents which act as complete carcinogens in some circumstances may act as carcinogen-modifying agents in other circumstances. Furthermore, no laboratory animal can be assumed never to have been exposed to carcinogens. If cancer arises in an animal exposed to a given carcinogen, it is impossible to determine what role the carcinogen played in causing cancer; it may merely have increased the risk of cancer developing from an unknown cause. (3 references)

- 5022 MAMMARY GLAND CARCINOGENESIS IN WOMEN (EPI-DEMOLOGICAL AND CLINICAL DATA). (Rus.) Levshin, V. F. (I. M. Sechenov 1st Moscow Med. Inst., USSR). *Vopr Onkol* 18(7):97-108, 1972.

Epidemiological and clinical data on mammary gland carcinogenesis in humans are reviewed. The incidence is related to socioeconomic factors including number of children/woman, as well as to constitutional factors including hormonal excretion and menstrual function. As for the relationship between the incidence of mammary cancer and the number of births, there are two contradictory opinions. Some hold that women having few or no children are more likely to develop mammary gland cancer, while others believe that births are not a factor in mammary gland carcinogenesis. There are also contradictory data on the role of lactation in mammary gland carcinogenesis. Comparative studies of cancer patients and healthy persons do not confirm the roles of childbirth and lactation in carcinogenesis. The relationships between carcinogenesis and ovarian, steroid, and hypophyseal hormones have not been determined. A series of studies showed that there were functional nervous disorders in patients with mammary cancer. Changes in the nervous and endocrine systems may, therefore, have some effect on mammary carcinogenesis. Significant disorders in these systems can occur with minimal changes in the mammary gland. Also, mammary gland cancer can occur in the presence of insignificant steroid changes. (121 references)

- 5023 GENETIC FACTORS IN CARCINOGENESIS. (Ger.) Schroeder, T. M. (Inst. Anthropol. Human Genet., U. Heidelberg, West Germany). *Fortschr Med* 90(16):603-608, 1972.

Recent findings in four autosomal recessive diseases, Fanconi anemia, Bloom's syndrome, ataxia teleangiectasia and xeroderma pigmentosum, and their relevance to the etiology of neoplasias, are discussed. The association of chromosome changes in cancer cells and carcinogenesis may be due to chromosome mutations (Philadelphia chromosome) or constant deviations from the normal karyotype in meningiomas. Chromosome changes may not be primarily responsible for the origin of cancers, but may develop independently in the course of the disease. Another concept is that chromosome changes prepare the way for tumor development. Arguments for the mutation concept of carcinogenesis are presented in connection with the four diseases mentioned, based on DNA damage, spontaneous chromosome breakage and the subsequent rearrangement for the formation of clonal cell lines with abnormal chromosomes. In Japanese victims of the atom bomb radiation, chromosome aberrations and the high incidence of leukemia in children support this concept. It is not clear whether the primary cancer cells are developed from tumor-specific chromosome mutations, or whether these originate in a small clone before transference to the cancer cell. (19 references)

- 5024 THE MECHANISM OF CHEMICAL CARCINOGENESIS: ADVANCES AND PROBLEMS. (Ger.) Wunderlich, V. (Inst. Cancer Res., Berlin, West Germany). *Arch Geschwulstforsch* 38(3/4):310-326, 1971.

Recent research into the mechanisms of chemical carcinogenesis is reviewed. Of the chemical substances

implicated in carcinogenic activity the following groups are mentioned most frequently: polycyclic aromatic hydrocarbons; aromatic amides and amines; azo dyes; alkylating agents (including N-nitroso derivatives); and 4-nitroquinoline-N-oxide and derivatives. Reactive forms of chemical carcinogenesis are delineated, with particular mention of the recent theory that all chemical carcinogens are able to form electrophilic agents *in vivo*, which react with nucleophile groups in cellular macromolecules. Such interaction requires a receptor in the cell, which may be either nucleic acids or proteins. Special attention has been directed at changes in transfer RNA in carcinogenesis. Chemical carcinogens are known to effect molecular alterations in nucleic acids and in proteins; purine bases are especially altered in this connection. The direct chemical carcinogenic effects may be demonstrated by the induction of somatic mutations, in which DNA alterations occur. The individual phases of cancer development are detailed. Many former experiments, describing only a slight relationship between carcinogenesis and mutagenesis, are now considered to have employed an inadequate test organism. It has recently been shown that high genetic activity is compatible with the plasma mutation hypothesis of carcinogenesis. (26 references)

- 5025 IS BREAST CANCER IN MICE IDENTICAL WITH BREAST CANCER IN WOMEN? (Fr.) Hollmann, M. K. H. (Broussais Hosp., Paris, France). *Bord Med* 5(6):627-643, 1972.

The induction of mouse mammary tumors by a virus (MTV) transmitted in the mother's milk is recognized. The virus is an RNA oncornavirus present in all mouse mammary tumors. The particulate matter formed by the virus is called particle B. The manner of elaboration of B particles by cellular tumors appears to be associated with a swelling of surface membranes or with the formation of smaller particles called A particles. These particles are found in the cytoplasm, predominantly in the Golgi area. A tumor cell with intracytoplasmic A particles and B particles situated in the cytoplasmic vacuoles is illustrated. The chemical composition of the mammary tumors includes RNA, lipids, and possibly, polypeptides. Not all mice with this virus develop mammary tumors. Other factors in the development of carcinogenesis include the role of hormones (estrogens); genetic factors which influence hormonal responses and the susceptibility of the gland; and immunologic factors. The mouse tumor possesses an RNA-dependent DNA polymerase called reverse transcriptase. Arguments for a viral origin for human breast cancer are based on the presence of virus like particles in such cancers and in human milk; the presence of reverse transcriptase in some human milk; the presence of antibodies in human serum which neutralize the mouse tumor virus; the presence of 70S RNA in human milk; and the possibility of hybridization between the RNA from mouse tumors and the RNA extract of human mammary cancer. Therapeutic measures are delineated. (40 references)

- 5026 MUTANTS OF THE POLYOMA VIRUS. (Fr.)
Cuzin, F. (Inst. Pasteur, Paris, France).
Bull Cancer (Paris) 59(1):15-20, 1972.

Polyoma virus mutants are analyzed with respect to the molecular level of transformation. Two types of systems are distinguished: permissive and nonpermissive. In the permissive system, (mouse cells), the large majority of cells develop a lytic cycle and a small number survive the infection, some acquiring transformed characteristics. The successive events observed are penetration of the virus into the cell followed by decapsulation, synthesis of viral proteins, induction of the synthesis of cellular proteins (enzymes related to DNA), and viral DNA synthesis together with cellular DNA synthesis. The delayed events include protein synthesis of the viral capsule. In the nonpermissive (abortive) system (hamster cells), the initial events are similar, but it is not possible to detect viral DNA synthesis, and the delayed events are not observed. This infection does not produce viruses and the cells survive. Among these cells, some acquire a transformed phenotype. The various functions coded by the polyoma genome, particularly those responsible for the transformation of the cell, were investigated. Isolation of the thermosensitive mutants in a permissive system led to their classification into four complement groups: L1, L2, TSA and TS3. In the first two, the delayed function is blocked and during an infection at high temperature, there is no production of virus; but the initial events occur normally, particularly viral DNA synthesis. The viruses with these mutations transform the cells normally regardless of temperature. The TSA mutations inhibit viral DNA synthesis during lytic infection, but cellular DNA synthesis proceeds normally. Only a small number of the infected cells (abortive transformation) will produce stable clones which will maintain their transformed characters, and these will only last for two or three generations, after which they will return to a normal state. Two functions have been identified to date as necessary for transformation: one for the permanent hereditary fixation at the cellular clone level of the transformed state; and one which must be expressed continually so that the cell remains in this state. (No references)

- 5027 IS THERE A RISK OF CARCINOGENESIS BY BITUMENS? (Fr.) Siou, G. (No affiliation). *Rev Pathol Comp Med* 72(9):65-70, 73-75, 1972.

Bituminous products are reviewed in terms of physico-chemical, clinical and experimental findings relevant to their possible carcinogenic effects. These substances are mixtures of hydrocarbons which may be aliphatic, naphthenic or aromatic. In the bitumens, the saturated cyclic compounds predominate, in contrast to tars in which the carcinogenic cyclic aromatic compounds predominate. Although the bitumens are not carcinogenic, mixtures of bitumens and tar may still be carcinogens. In a 1968 survey, tumor development in 462 workers from seven different refineries was compared with that of 379 workers in

25 factories outside of the bitumen product industry. Although the refinery workers had been in contact with bituminous products for at least five years, their malignancy rate was not higher than in the other workers. Other evidence of this type is cited. While experiments with mice support the view that bitumens are carcinogenic, mice are not so susceptible to inhalation of bituminous fumes. The conditions for the animal experiments cannot be compared with the type of contact humans have with these products. Thus, there is no evidence at present of a risk of carcinogenesis in working with bitumens. (25 references)

- 5028 RNA ONCOGENIC VIRUSES AND MALIGNANT TRANSFORMATION. (Fr.) Du Pasquier, P. (Hosp. Pellegrin, Bordeaux, France), P. Grimont and J. C. Auriol. *Bord Med* 7:753-762, 1972.

A virus coming in contact with a cell will cause infection if the cell contains specific receptors permitting the fixation and penetration of the virus into the cytoplasm. The virus is then denuded of its protein capsule and of the viral nucleic acid. The relationships between the cell and the virus may develop in various fashions: by the lytic or infectious cycle (permissive cells); a chronic infection of the cellular culture; the abortive cycle (with nonpermissive cells); the abortive cycle with a defective virus; or by a malignant transformation. Oncogenic viruses with RNA are essentially responsible for animal leukemias (possibly also in humans). They form a homogeneous virologic group: nucleic capsules with helicoid symmetry, genetic information carried by RNA, and an envelope which is produced from the cytoplasmic membrane. The four modes of replication of these viruses are described. Cells transformed by the oncogenic viruses acquire new properties: a loss of the contact inhibition; morphologic alterations; an increase in growth rate; the possibility of subcultures *in vitro*; metabolic alterations; chromosomal anomalies; a reduced capacity of supporting the multiplication of certain infectious viruses; resistance to a reinfection by the transforming virus; the appearance of new cellular antigens; and the capacity to form cancers in hosts by transplantation or injection. - 5029 TUMOR IMMUNOLOGY: A PROBLEM OF MEMBRANE RESEARCH? (Ger.) Uhlenbruck, G. (Med. Univ. Clin., Cologne, West Germany) and U. Reifenberg. *Med Klin* 66(43):1435-1441, 1971.

An overview of tumor immunology includes: types of defense reactions, such as a normal immune activity, the formation of humoral antibodies, or an immune reaction similar to that against a transplant; measures by which immunity can be transferred to individuals with immunity defects, such as transfusion of humoral antibodies or immunologic-competent lymphocytes; and the role of the tumor cell membrane in this context. Some of the work carried out on membrane changes includes experiments with tumor cell charge,

methods of strengthening the antigen profile, and the treatment of tumor cells with enzymes. This treatment is described under the headings of glycosidases (particularly neuraminidase) and the proteolytic enzymes. A-like antigens, heterophilic antigens occurring in erythrocytes of the Cad blood group, consist of an end-N-acetyl-D-galactosamine linked by means of an α -glycosidic bond to an unknown carrier. The A-like antigens are reviewed, and the relationship between blood group antigens, tumor cell characteristic antigens and alterations in the cell membranes of tumor cells is shown in a diagram. The growth of malignant cells and the effect of agglutinin is illustrated in another diagram, involving the role of the tumor membrane. Therapeutic consequences of the most recent concepts are discussed. (29 references).

- 072 TUMOR INHIBITION, PERSISTENCE, AND BINDING OF ACTINOMYCIN D IN MOUSE SKIN. (E.)
 Regal, A. (New York U. Sch. Med., N.Y.), T. Honohan, I. Schroeder, C. Katz and B. L. Van Duuren. *Cancer Res* 32(7):1384-1390, 1972.

Female ICR/Ha Swiss mice were given 2 µg actinomycin D (AMD) by topical application to dorsal skin 31 days after treatment with 7,12-dimethylbenz(a)anthracene (DMBA) and 90 days before treatment with phorbol myristate acetate (PMA), a DMBA carcinogenesis promoter. Papilloma development was reduced by 63% in mice given AMD. Inhibition was 61% when AMD was given 90 days after DMBA and 14 days before PMA. AMD could be isolated from mouse skin until six days after application (3% of the AMD dose was recovered at this time). When AMD-methyl-¹⁴C (AMD-¹⁴C) was applied to mouse skin, 0.042% of the dose applied could be recovered in skin 28 days after application. Skins treated with AMD-¹⁴C were extracted with ethyl acetate, methanol or water; the results suggested that AMD bound to mouse skin in several different ways. Radioactivity was demonstrated in extracted skin; this radioactivity appeared to be unchanged AMD-¹⁴C. Eighty-eight percent of residual reactivity could be extracted with 4 M CsCl in 0.01 M Tris HCl at pH 8, while AMD-¹⁴C bound to mouse liver DNA could not be extracted. This suggested that AMD-¹⁴C was not bound to DNA. Autoradiography of AMD-¹⁴C-treated skins revealed that AMD persisted around hair follicles. No radioactivity was seen localized over cells (cytoplasm or nuclei).

- 5073 GROWTH KINETICS OF DIETHYLNITROSAMINE-INDUCED, ENZYME-DEFICIENT "PRENEOPLASTIC" LIVER CELL POPULATIONS *IN VIVO* AND *IN VITRO*. (E.)
 Rabes, H. M. (Inst. Path., U. Munich, West Germany), P. Scholze and B. Jantsch. *Cancer Res* 32(11):2577-2586, 1972.

Rats fed 5 mg diethylnitrosamine/kg/day died from hepatocellular carcinoma after 138.0 ± 10.7 days ($n=258$). Thirty days after start of feeding, circumscribed areas of deficiencies of glucose 6-phosphatase and adenosine triphosphatase appeared in the enzyme histochemical preparation of the liver. The number of enzyme-deficient areas increased approximately exponentially until the 70th day, after which it remained stationary. The enzyme-deficient areas of the liver sections were grouped into 54 classes according to size as measured by planimetry (increment/class, 0.9584 sq mm) as a function of time. The results showed that only areas of Class 1 to 8 (0.0584 to 0.467 sq mm) were present until the 80th day. Thereafter the number of larger areas up to Class 54 (3.154 sq mm) increased discontinuously. In autoradiograms prepared after seven injections of thymidine-³H at 6-hr intervals, at early stages the labeling index of hepatocytes of enzyme-deficient areas was not significantly different from the surrounding parenchyma. From the 90th day onward, however, it greatly increased in individual enzyme-deficient areas, while others maintained a low labeling index. Hepatocytes from nodular enzyme-deficient portions of liver tissue of diethylnitrosamine-

fed rats proliferated *in vitro*, in contrast to those of normal adult liver of control rats. The thymidine-³H labeling index of these cultured hepatocytes 30 min after addition of thymidine-³H differed by a factor of about 25 between individual liver explants of diethylnitrosamine-fed rats under standardized culture conditions. Foci of enhanced proliferation were seen within slowly proliferating hepatocytes. The varying behavior of the enzyme-deficient cell populations, as demonstrated *in vivo* and *in vitro*, indicates that they are not a homogeneous preneoplastic population but rather potentially preneoplastic cells in various stages of development. Rapidly proliferating subpopulations of the enzyme-deficient cell groups might be foci of origin of hepatocellular carcinomas.

- 5074 NEWER CONCEPTS OF CANCER OF THE COLON AND RECTUM: SIMILARITIES BETWEEN HUMAN AND EXPERIMENTALLY INDUCED TUMORS OF THE LARGE INTESTINE. (E.) Spjut, H. J. (Baylor Coll. Med., Houston, Tex.). *Dis Colon Rectum* 15(2):94-99, 1972.

The induction of intestinal neoplasms by 3-2'-dimethyl-4-aminobiphenyl (DMAB) was studied in male and female white Wistar rats which received the compound (2 mg/100 g body wt) according to a variety of experimental procedures. The types of experimentally induced neoplasms and their patterns of induction and growth were compared with those of previously observed human colonic tumors. The DMAB-induced rat intestinal neoplasms were grossly similar to human tumors in that the majority of both the benign and malignant lesions were polypoid. As with human tumors, the larger rat intestinal tumors tended to be malignant. In experimentally induced colonic neoplasms and those that occur in the human, the incidences of the neoplasms in males and females were fairly similar. The distributions of DMAB-induced rat intestinal neoplasms and those seen in the human large intestine were similar. Like humans, animals bearing colonic neoplasms were prone to develop other tumors in other parts of the body. No ultrastructural differences were observed between the benign and malignant intestinal neoplasms of the rat and human. Unlike human colonic tumors, however, the DMAB-induced rat intestinal neoplasms did not metastasize.

- 5075 LYSOSOMAL ENZYME ACTIVITY AS AFFECTED BY AFLATOXIN AND MITOMYCIN C. (Rus.)
 Pokrovskiy, A. A. (N. I. Pirogov 2nd Med. Inst. Moscow, USSR), L. V. Kravchenko and V. A. Tutel'yan. *Biokhimiya* 36(4):690-696, 1971.

Lysosomal enzymes as affected by aflatoxin and mitomycin C were studied. Aflatoxin (15 mg/kg) was administered through a gastric catheter to one group of Wistar rats. Mitomycin C (2.5 mg/kg) was administered i.p. in another group of rats. The animals were killed 1-96 hr after the introduction of antibiotics to obtain liver homogenates and lysosomal fractions. The following six lysosomal enzymes were studied spectrophotometrically: DNase, arylsulfatases A and B, β -glucuronidase, β -acetylglucosaminidase,

β -galactosidase, and β -glucosidase. The activity of the liver lysosomal enzymes increased after aflatoxin introduction. In three hr, DNase activity reached 168% of the control level; Arylsulfatases A and B and β -glucuronidase increased to 141.5 and 121%, resp. These enzymes reached maximum levels in approximately 49 hr. An electron microscopic study showed a significant increase in the number of lysosomes in the liver cells during these periods. Mitomycin C led to decreases in most enzymes studied: β -glucosidase decreased two times; β -glucuronidase and β -acetylglucosaminidase were 86 and 88% of the control volumes in three hr, remaining more or less at the same levels for 6-96 hr.

- 5076 URINARY 7-METHYL GUANINE EXCRETION OF THE RAT AFTER A SINGLE APPLICATION OF DIFFERENT CARCINOGENS. (Ger.) Weyland, P. (Max-Planck Inst. Biochem., Munich, West Germany), H. J. Gross and H. Dannenberg. *Z Krebsforsch* 77:141-149, 1972.

Urinary 7-methyl guanine excretion of Sprague-Dawley rats was followed up to 21 days after a single high dose of the carcinogens: dimethyl nitrosamine, diethyl nitrosamine, N-nitroso morpholine, trans-dimethylamino stilbene, and 9,10-dimethyl-benzanthracene. The carcinogens were administered orally or by i.p. injection. The normal amount of 7-methyl guanine excreted by rats was 210-255 γ /day. A perceptible increase in 7-methyl guanine excretion occurred only in the case of dimethylnitrosamine, in four animals who died on the third day after i.p. administration of 30 mg/kg of the compound. In the surviving animals, after an increase on the first day, there was a transitory drop with a minimum at 3 days. The other carcinogens all caused an immediate decrease in urinary 7-methyl guanine excretion which lasted six-nine days. Increased excretion of 7-methyl guanine may be due to the methylation of guanine in nucleic acids by dimethylnitrosamine along with normal degradation, with a further increase caused by depurination of the methylated nucleic acid. Decreased excretion may be due to damage to the kidneys, or a slow degradation of nucleic acids by the inhibition of nuclease, a decrease in methylation or an increase in degradation of 7-methyl guanidine.

- 5077 ONCOGENICITY OF 1-(4-CHLOROPHENYL)-1-PHENYL-2-PROPYL CARBAMATE FOR RATS. (E.) Harris, P. N. (Eli Lilly Co., Greenfield, Ind.), W. R. Gibson and R. D. Dillard. *Toxicol Appl Pharmacol* 21(3):414-418, 1972.

Male and female rats, aged four to six wk, were fed 1-(4-chlorophenyl)-1-phenyl-2-propyl carbamate as 0.025, 0.05 or 0.1% of their diet. All but four of 60 rats given the compound developed tumors; 36 rats had multiple tumors of the same type and 26 had more than one type of tumor. Tumors developed earlier in females than in males, and in females the commonest type of tumor was mammary adenocarcinoma. The most common tumor types in males were duodenal and upper jejunal tumors. Other tumors which developed were intracranial tumors, oral carcinomas, Wilms' tumor and glioma.

- 5078 THE CYTOTOXIC EFFECT OF ETHYLNITROSOUREA AND METHYLNITROSOUREA ON THE NERVOUS SYSTEM OF THE RAT AT DIFFERENT STAGES OF DEVELOPMENT. (E.) Bosch, D. A. (Dept. Path., U. Groningen, Netherlands), P. O. Gerrits and E. J. Ebels. *Z Krebsforsch* 77(4):308-318, 1972.

Rats one to 30 days old were injected with ethylnitrosourea (ENU) or methylnitrosourea (MNU) in amounts ranging from 20-240 mg/kg. Six hr after ENU or MNU administration, the rats were sacrificed and degree of cell damage was observed in the central nervous system; the peripheral nervous system, including trigeminal nerves and Gasserian ganglia; intestines and kidneys. In rats given 240 mg/kg ENU, a distinct cytotoxic effect was seen only in areas of active cell proliferation; degenerative cells in the central nervous system were confined to matrices and cell streams originating from them. Cells concerned with myelination were most involved in trigeminal nerves, while capsule cells were most involved in Gasserian ganglia. Cytotoxic changes were also seen in intestinal crypts and in kidney cells. Nondividing cells were resistant to the cytotoxicity of the agents. The cytotoxicity of ENU and MNU appeared to depend on the amount of alkylating groups administered in a dose. Equimolar doses of ENU and MNU produced equal proportions of lethally damaged cells and equal degrees of mitotic inhibition. Above 120 mg/kg of ENU or MNU, mitotic inhibition was complete.

- 5079 EFFECT OF DIETHYLNITROSAMINE (DENA) AND INFLUENZA VIRUSES ON THE INDUCTION OF LUNG CARCINOMAS IN MICE. (Ger.) Schmidt-Ruppin, K. H. (Pharmaceutic Res. Lab. J. R. Geigy AG, Basel, Switzerland), G. Papadopolu. *Z Krebsforsch* 77:150-154, 1972.

Groups of NMRI mice (20-25 g) were injected (nasal route) every four wk for six months with 0.05 ml ml Hanks solution containing sublethal doses (LD 10) of the influenza viruses A₂/Bethesda 10/63 (group A) and PR8/EIK (group B), or Hanks solution alone (group C). Surviving mice (39 out of 50 group A, 31 out of 60 group B and 25 out of 50 group C) were then fed diethylnitrosamine (DENA) in daily drinking water (5 ml containing 0.04 mg/ml DENA) for an additional six months (total: 36 mg/animal or 1080 mg/kg). A statistically significant increase in primary lung carcinoma was observed in surviving animals of groups A (78.2%) and B (58.3%) as compared with those of group C (10.5%), suggesting a strong cocarcinogenic activity of influenza virus and DENA.

- 5080 TUMORIGENICITY OF FIVE CYCLIC NITROSAMINES IN MRC RATS. (E.) Garcia, H. (Eppley Inst., Res. Cancer Omaha, Nebr.) and W. Lijinsky. *Z Krebsforsch* 77(4):257-261, 1972.

Thirty MCA rats were given 2 mg of one of the following nitrosamines in their drinking water, five days/wk for 50 wk: nitrosopiperidine, nitroso-morpholine, dinitrosopiperazine, nitrosoheptamethyleneimine, and N-nitroso-3-pyrroline. Nitrosoheptamethyleneimine caused a total of 26 squamous

5081-5084)

tumors in trachea, lung, esophagus and nasal cavities. Nitrosopiperazine caused a total of 14 tumors in liver and nasal cavities. Nitrosomorpholine caused a total of 19 tumors in liver, esophagus and nasal cavities. Nitrosopiperidine caused a total of 30 tumors in trachea, pharynx, larynx, liver, esophagus and nasal cavities. N-nitroso-3-pyrroline was the weakest carcinogen of the five; it caused a total of four tumors in liver and nasal cavities. Reasons for the pronounced organ specificities of the five nitrosamines are discussed.

5081 QUANTITATION OF ARYL HYDROCARBON HYDROXYLASE ACTIVITY IN INDIVIDUAL FETAL HAMSTER CELLS *IN VITRO*. (E.) Kouri, R. E. (Inst. Radiat. Biol., U. Tennessee, Knoxville), R. A. Lubet and D. Q. Brown. *J Nat Cancer Inst* 49(4):993-1005, 1972.

Aryl hydrocarbon hydroxylase (AHH) activity in individual fetal hamster cells was quantified by using a new microfluorometric technique. Treatment of fetal hamster cells with benzo(a)pyrene (BP) was followed by increased fluorescence at 520 nm. Several experiments indicated that the increased green fluorescence presented hydroxylated BP metabolites and was related to AHH activity. This fluorescence had the same spectrum as 3-hydroxybenzo(a)pyrene (3-OH BP), and the increase in fluorescence was related to the age of the hamster fetuses and the concentration of BP. Cells lacking AHH showed no increase in fluorescence, and chemicals known to inhibit or induce AHH activity altered the fluorescence accordingly. Amounts of extracellular 3-OH BP extracted from the culture medium paralleled intracellular concentrations, and ratios of extracellular to intracellular 3-OH BP allowed for an estimated average turnover time of 15 minutes for this metabolite. The rapid turnover rate suggested that amounts of intracellular 3-OH BP measured at a given time was an index of the number of active enzyme sites or the relative activity of these sites. Thus this microfluorometric technique can be used to describe the cytologic distribution of BP and its major metabolites, and to quantitate the amount of AHH metabolism proceeding at a given time.

5082 A STUDY OF H-PROTEINS IN THE LIVER OF ANIMALS WITH VARIED SENSITIVITY TO CARCINOGENIC SUBSTANCES. (Rus.) Kaledin, V. I. (Inst. Cytol. Genet., Siberian Branch, Acad. Sci. USSR, Novosibirsk). *Vopr Onkol* 18(6):57-60, 1972.

Extracts of the livers of Wistar rats, CC57Br and C3H mice, hamsters, guinea pigs, and rabbits were obtained by centrifuging standard homogenates of the liver of individual animals. The animals received azo dyes through the esophagus; the rats received 10 mg 4-dimethylaminoazobenzene (DAB); the mice received 5 mg aminoazotoluene or s.c. injections of 2.5% solution of DAB and azobenzene (15 mg/100 g). H-protein preparations were obtained from liver extracts by a chromatographic method. The h-protein level was studied by a radial agar immunodiffusion method. A total of five protein preparations containing DAB was obtained. An immunological

analysis of these preparations showed two fractions--h-A and h-B. With the aid of antisera obtained against the isolated protein, it was determined that both fractions from the liver of animals sensitive to carcinogenic aminoazo dyes were not specific (to these animals). But h-protein fractions not combining with carcinogens were not identical with h-proteins of the rat liver in terms of antigenic specificity and electric charge. Thus, differences in the sensitivity to carcinogens are related to the variable level of h-protein fractions in the organs. There was a correlation between the content of h-protein in the liver of adult white rats and mice and their sensitivity to the carcinogens. Thus, combination with h-protein fractions is a condition of the carcinogenic effect of azo dyes and aromatic amines.

5083 STUDIES OF MAMMARY CARCINOMA INDUCED BY 7,12-DIMETHYLBENZ(a)ANTHRACENE ADMINISTRATION. (E.) Murad, T. M. (Div. Clin. Cytol., Ohio State U., Columbus) and E. von Haam. *Cancer Res* 32(7):1404-1415, 1972.

Seventy-two female rats were injected i.v. with 2 mg of 7,12-dimethylbenz(a)anthracene (DMBA); 173 mammary carcinomas developed. These were observed during their development by light and electron microscopy. Multiple tumors and tumors with different histological patterns often appeared on the same rat. Surgical removal of the first primary tumor did not prevent further tumor development; however, no metastases were seen in any DMBA-treated rat. The earliest change in breast tissue was focal hyperplasia of the lining cells of the secretory units. Both epithelial and myoepithelial cells participated in the early stages of tumorigenesis; stromal tissue also showed early proliferation. The enzyme alkaline phosphatase continued to be reactive on the plasma membranes of proliferating myoepithelial cells. Tumors were removed from five to ten wk after DMBA. Seven tumor types were seen: adenoid cystic carcinoma, adenocarcinoma, solid medullary carcinoma, papillary carcinoma, follicular and pseudofollicular carcinoma, myxoid carcinoma and *in situ* ductular (lobular) carcinoma. Proliferation of epithelial and myoepithelial cells, when present in relatively equal proportions, may be the cause for the absence of metastases.

5084 ENHANCEMENT BY PHENOBARBITAL OF 2-ACETYLAMINOFLUORENE-INDUCED HEPATIC TUMORS IN THE RAT: CONSEQUENCES OF VARIOUS TEMPORAL COMBINATIONS OF 2-ACETYLAMINOFLUORENE AND PHENOBARBITAL TREATMENTS. (E.) Peraino, C. (Argonne Natl. Lab., Ill.), R. J. M. Fry and E. Staffeldt. *Argonne Nat Lab Ann Report* 7770:44-45, 1971.

Rats were fed 2-acetylaminofluorene (AAF) as 0.02 or 0.05% of diet; after AAF feeding, some rats were given phenobarbital in various regimens. Liver tumor incidence was increased by phenobarbital; rats given AAF only had a 4.2% tumor incidence by 164 days after the start of the experiment, while rats given phenobarbital and AAF had a 42.9% tumor incidence.

Shortening exposure to phenobarbital reduced but did not abolish enhancement of AAF tumorigenesis. Delaying administration of phenobarbital for ten days after AAF increased tumor incidence over that seen when phenobarbital was given immediately after AAF.

- 5085 THE ROLE OF THE KIDNEYS IN DISORDERS OF PORPHYRIN METABOLISM DURING CARCINOGENESIS INDUCED WITH LEAD ACETATE. (E.) Zawirska, B. (Med. Sch., Wrocław, Poland) and K. Medras. *Arch Immunol Therap Exp (Warsz)* 20:257-272, 1972.

Rats aged 215 days were fed lead acetate (3 mg/rat/day) for 60-504 days and porphyrin contents of kidneys, liver, bone marrow and 24-hr stools and urine were observed. Rats fed lead acetate developed hyperplasia in different organs and showed increased porphyrin contents compared with rats not fed lead acetate. The increase in porphyrin contents was especially conspicuous in rats fed lead acetate for 307 days or longer. Increases in porphyrin levels were more pronounced in male than in female rats. Porphyrin levels, and especially uroporphyrin levels, were especially high in kidneys of treated rats; in some cases, the amount of uroporphyrin in kidneys exceeded that in other organs by as much as 3-5-fold. Differences in porphyrin contents in urine and stools between lead acetate-fed rats and control rats were not statistically significant.

- 5086 *IN VIVO* AND *IN VITRO* STUDIES ON UTERINE ADENOCARCINOMA OF THE RAT INDUCED BY 7,12-DIMETHYLBENZ(A)ANTHRACENE. (E.) Sekiya, S. (Sch. Med., Chiba U., Japan), H. Takamizawa, F. Wang, T. Takane and T. Kuwata. *Am J Obstet Gynecol* 113(5):691-695, 1972.

Pellets of 7,12-dimethylbenz(a)anthracene (DMBA) were placed in the gestation sacs of rats pregnant for 10-12 days. Histologically different tumor types were induced, but adenocarcinoma was the most common. Uterine adenocarcinomas 219 and 314 days after DMBA treatment were established in culture. Outgrowth of epithelial cells was seen by two months after establishment of cultures, and epithelial cell cultures showed active proliferation. When the cultured epithelial cells were implanted s.c. into isologous rats, tumors developed which metastasized to viscera; the metastases had the histology of adenocarcinomas. Two distinct types of clonal lines were established from adenocarcinoma cells in culture: a highly tumorigenic clone (HTP) and a weakly tumorigenic clone (LTP). HTP was isolated from adenocarcinoma cells cultured in semisolid agar medium, LTP from tumor cells cultured in liquid medium. HTP and LTP cloned cells differed in colony-forming ability in semisolid agar and in tumorigenicity in isologous hosts.

- 5087 AUTORADIOGRAPHIC CHARACTERISTIC OF EXPERIMENTAL THYROID TUMORS IN RAT. (E.) Christov, K. (Cancer Res. Inst., Sofia, Bulgaria). *Endokrinologie* 59(3):382-390, 1972.

Male and female rats were treated with i.p. or oral doses of 30 μ Ci 131 I given alone or together with methylthiouracil (MTU). Thyroids of untreated and 131 I- and/or MTU-treated rats were removed between 365-600 days and subjected to autoradiography to detect organically bound 131 I (control rats, not otherwise treated, were nevertheless given 131 I in one dose for autoradiography). Thyroid follicles of control rats accumulated considerable 131 I. Most of the 107 epithelial tumors seen in the 80 thyroids examined developed in rats given 131 I and MTU; few tumors accumulated 131 I. Those tumors which did take up 131 I were usually of the follicular type. Most papilliferous tumors did not take up 131 I. Carcinomas were found only in rats given 131 I and MTU; most carcinomas lacked 131 I uptake.

- 5088 EXPERIMENTALLY INDUCED TUMORS OF THE PERIPHERAL NERVOUS SYSTEM IN THE DOG. (Ger.) Stavrou, D. (Vet. Med. School, U. Munich, West Germany) and K. G. Haglid. *Naturwissenschaften* 59(7):317-318, 1972.

The neuro-oncogenic effect of N-methyl-nitrosourea was tested in dogs who were injected with a single dose of 20 mg/kg at 30-day intervals up to the time of death. Three of the six animals died during the seventh or eighth month and the other three were found to have tumors in the 21st, 23rd and 25th month, resp. Tumor sites were in the heart, the duodenum and the cauda equina, resp. The dog with the peripheral nervous system (PNS) duodenal tumor also exhibited multiple hemangioendotheliomas in various organs (brain, spinal column, lungs, spleen). The other two dogs with neurinomas suffered a diffuse hemorrhagic diathesis terminally. The histological examination revealed well-differentiated PNS tumors with typical schwannoma structures. The results demonstrate that PNS tumors may be induced in dogs, as well as in rodents, with N-methyl-nitrosourea.

- 5089 HISTOLOGICAL AND AUTORADIOGRAPHICAL STUDIES ON INTESTINAL TUMORS OF RAT INDUCED BY ORAL ADMINISTRATION OF N,N'-2,7-FLUORENYLENEBISACETAMIDE. (E.) Yamada, S. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan), M. Ito and T. Nagayo. *Gann* 62(6):471-478, 1971.

Buffalo rats were fed a diet containing 0.025% N,N'-2,7-fluorenylenebisacetamide (2,7-FAA) beginning at age one to three months. Intestinal tumors occurred in 51.1% of 188 rats which survived 100 days of 2,7-FAA feeding. Tumor incidence in male rats was 56.5%, in females, 49.9%. Half of all intestinal tumors arose in the terminal ileum or ascending colon. The average number of tumors/rat was 3.8; more females than males had only one tumor/rat. Most tumors were 1 cm or less in diameter and most were adenomas. Tumors were classified as hemispheric, plateau, polypoid, polyp and umbilicated. Histological atypism was most common in umbilicated tumors; lymph node metastases were associated with 12.5% of these tumors. Some rats fed 2,7-FAA were injected with 3 H-thymidine for autoradiographic study. One hr postinjection,

³H-thymidine was seen only in proliferating cells of the intestinal mucosal glandular epithelium in rats not fed 2,7-FAA. In tumor-bearing rats fed 2,7-FAA, label was distributed diffusely in neoplastic tissue.

- 5090 THE STUDY OF C-CELLS OF THE THYROID IN RATS IN TUMOR INDUCTION. (Rus.) Kashulina, A. P. (P. A. Gertsen Res. Inst. Oncol., Moscow, USSR) and L. I. Rybakova. *Vopr Onkol* 18(8):62-64, 1972.

The state of thyroid gland C-cells in various stages of experimental blastomogenesis was studied in rats. Methylcholanthrene dissolved in peach oil (2 mg/100 g body wt) was administered s.c. to Wistar rats. Thyroid glands were studied 1-7 months after 20-methylcholanthrene introduction by Gomori's method, using paraldehyde-fuchsin coloring. C-cells were orientated toward the blood vessels and localized in interfollicular spaces of the peripheral sections of the gland. In rats receiving 20-methylcholanthrene, Gomori positive granules increased together with degenerating and pycnotic cells. Thus, changes indicating a weakening of the functional activity of C-cells were observed in early stages (1-3 months) of chemical carcinogenesis. These changes intensified with tumor progression.

- 5091 CARCINOGENICITY AND NEUROTOXICITY OF CYCASIN WITH SPECIAL REFERENCE TO SPECIES DIFFERENCES. (E.) Hirono, I. (Gifu U. Sch. Med., Japan). *Fed Proc* 31(5):1943-1947, 1972.

Tumor development in mice (dd strain), rats, hamsters, rabbits and guinea pigs given single s.c. or intragastric doses of cycasin was compared. Rabbits and guinea pigs failed to develop tumors after cycasin administration. In rats, kidneys and intestines were the main target organs, while the liver was the main target in mice and hamsters. Hepatocellular carcinomas were seen most often in mice, while intrahepatic bile duct alterations were the main lesions in hamster livers. Hepatocellular carcinomas, common in newborn hamsters, were not seen in adults. Cycasin was found to produce neurologic disorders, associated with necrosis of the external granular-layer of the cerebellum, in mice and hamsters.

- 5092 THE METABOLISM AND CARCINOGENICITY OF 2-ACETAMIDONAPHTHALENE. (E.) Conzelman, G. M., Jr. (Christ Hosp. Inst. Med. Res., Cincinnati, O.) and L. E. Flanders, III. *Proc West Pharmacol Soc* 15:96-99, 1972.

The metabolism of 2-acetamidonaphthalene was studied in urine of beagle dogs given a single 25 mg/kg oral dose of the compound or 65 mg/kg doses daily, six days/wk, for 21-24 months. Twenty-four hr urine specimens from dogs given 25 mg/kg 2-acetamidonaphthalene contained <3% of the dose as ortho-hydroxy amines and <2.5% as free diazotizable aromatic amines. Ninety percent of the 2-acetamidonaphthalene dose was ex-

creted. Urine specimens from dogs given the 65 mg/kg dose contained at least four metabolites which were diazotizable after acid hydrolysis. One of these metabolites was 2-acetamido-6-naphthyl glucuronide. No urinary bladder tumors were seen in any animal given the chronic dosage of 2-acetamidonaphthalene.

- 5093 SPECIFICITY OF TRANSFER RIBONUCLEIC ACID METHYLASES FROM NORMAL MOUSE COLON AND 1,2-DIMETHYLHYDRAZINE-INDUCED COLON TUMORS. (E.) Pegg, A. E. (Middlesex Hosp. Med. Sch., London, England). *Biochem J* 129(3):40, 1972.

The methylation of several tRNA species from *E. coli* and purified yeast by extracts of normal mouse colon and of 1,2-dimethylhydrazine-induced colonic tumors was studied. The following tRNA preparations from *E. coli* were found to be substrates for the formation of the methylated bases indicated (in parentheses): glutamic acid tRNA (5-methylcytosine and 1-methyladenine); serine tRNA₃ (5-methylcytosine, 1-methyladenine, *N*²-methylguanine and *N*²*N*²-dimethylguanine); formylmethionine tRNA (1-methyladenine, *N*²-methylguanine, 1-methylguanine and 5-methylcytosine). Phenylalanine and arginine tRNA from yeast were not methylated, but other tRNA preparations were. Enzymes from tumor tissue produced products with each of the substrates, similar to those found with tRNA's from normal colon. However, the rate and extent of methylation were greater with the tumor tRNA extracts than with normal extracts.

- 5094 ELECTRON SPIN RESONANCE STUDY ON THE FREE RADICAL PRODUCTION FROM N-METHYL-N'-NITRO-N-NITROSOGUANIDINE. (E.) Nagata, C. (Nat'l. Cancer Res. Inst., Tokyo, Japan), M. Nakadate, Y. Ioki and A. Imamura. *Cann* 63(4):471-481, 1972.

N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was stirred with a magnetic stirrer or exposed to photoirradiation from a mercury lamp (wavelengths below 340 nm shielded); the electron spin resonance (ESR) spectra of stirred and irradiated samples were measured to study the production of free radicals by stirred and irradiated MNNG. A free radical with a characteristic ESR signal was produced from MNNG after only one hr of stirring. The free radical was stable; only a small decrease in ESR signal was seen after 170 days from stirring. The amount of free radical produced by stirring depended on pH; the optimum pH was 3-6, N-Ethyl-, N-propyl-, and N-butyl-N'-nitro-N-nitrosoguanidine were not converted to free radicals with clear ESR signals by magnetic stirring. Photoirradiation of MNNG for five minutes produced a free radical with an ESR similar to that of the radical produced by stirring. Wavelengths longer than 340 nm were effective in producing radicals, indicating that the genesis of the free radical was correlated with n- π^* transition at 400 nm. Photoirradiation also converted N-ethyl-, N-propyl-, and N-butyl-N'-nitro-N-nitrosoguanidine to free radicals with characteristic MNNG signals. Photoirradiated dimethylnitrosamine, gave no ESR signal (i.e., was not converted to a free radical). A carcinogenic

role is postulated for the free radical produced by MNNG.

- 5095 ON PENETRATION OF 3,4-BENZOPYRENE IN THE ORGANISM. (Rus.) Dorogokuplya, A. G. (Inst. Exp. Clin. Surg., Alma-Ata, USSR), A. I. Myasnikov, N. E. Zhirnova and A. N. Ninichenko. *Vopr Onkol* 18(8):70-72, 1972.

Benzo(a)pyrene is contained in smoked food products such as smoked sausage. The possibility of benzo(a)pyrene penetrating the body through such food products was studied. Four dogs received 1.0 kg smoked sausage and 1 liter sour cream. Three hr later blood and thoracic lymph samples were analyzed. In all animals, benzo(a)pyrene levels were higher in the lymph (0.01-0.014 γ /ml) than in the blood (0.0001-0.0003 γ /ml). This shows that benzo(a)pyrene penetrates the body through intestinal lymphatic ducts, the blood, and then organs. Invasion of the body by the carcinogen in the air was studied in 25 white rats exposed to air containing 8-36 mg/m³ benzo(a)pyrene. All 25 rats showed the carcinogen in various organs. Most rats showed benzo(a)pyrene in the lungs, trachea, and bronchi. In nine rats, the benzo(a)pyrene level in the gastric juice was 0.002-0.004 γ /g. Thus the carcinogen invaded the body via the respiratory tract (lung, trachea, and bronchi) and penetrated to the digestive organs (stomach). Twelve blood donors were on a diet containing 0.4 kg smoked sausage and 0.25 kg sour cream. Benzo(a)pyrene was detected in the blood of these donors three hr after eating. Benzo(a)pyrene level in the blood of 10 diesel automobile operators was 0.000003-0.0001 γ /ml.

- 5096 AN EXPERIMENTAL STUDY OF THE CARCINOGENIC EFFECT OF TUBAZID (ISONIAZID) AND PHTHIVAZID. (Rus.) Pershin, G. N. (S. Ordzhonikidze All-Union Pharm. Chem. Res. Inst., Moscow, USSR), O. O. Makeeva, A. A. Grushina and V. A. Chernov. *Vopr Onkol* 18(6):50-53, 1972.

The carcinogenic effects of Tubazid and Phthivazid in aqueous solution were studied in healthy white mice. One group of mice (100) received 1 mg Tubazid; a second group (100) received 2 mg phthivazid; and a third group (100) did not receive any drugs. Sixteen animals in the first group, 19 in the second group, 11 in the third group died within eight months. The animals were killed to study their internal organs. Tumors were detected in 7.4% of the control group, 35.7% of the Tubazid group, and 23.3% of the Phthivazid group. In the first group, adenomas of the lungs were seen in 27.6% and mammary gland tumors in 8.2%. Similarly, adenomas of the lungs were seen in 15.6% and mammary gland tumors in 7.8% in the second group.

- 5097 MACROPHAGES AND MULTINUCLEATE GIANT CELLS IN NITROSOQUINOLINE-INDUCED GRANULOMATA IN RATS: AN AUTORADIOGRAPHIC STUDY. (E.) Carter, R. L. (Royal Cancer Hosp., London, England) and J. D. B. Roberts. *J Pathol* 105(4):285-288, 1971.

Male Wistar rats were injected s.c. with 25 mg N-nitroso-2,2,4 trimethyl-1,2-dihydroquinoline (NTDQ); after NTDQ, the rats were injected with ³H-thymidine. Seven to 63 days after NTDQ, injection-site granulomas were removed and examined autoradiographically. By seven days, many macrophages were seen in granulomas. Multinucleate giant cells had replaced macrophages as the most prominent cells in the granulomas by 14-20 days. The turnover of macrophages was not uniform; short-lived and longer-lived macrophage populations were in evidence. Short-lived as well as long-lived macrophages took up NTDQ; macrophages which took up large amounts of NTDQ showed no nuclear labeling with ³H-thymidine. ³H-thymidine was also absent in giant cell nuclei. This indicated that giant cells were formed by fusion of macrophages which did not synthesize DNA.

- 5098 α -FETOPROTEIN AND HEPATOCARCINOGENESIS IN RATS FED 3'-METHYL-4-(DIMETHYLAMINO)-AZOBENZENE OR N-2-FLUORENYLACETAMIDE. (E.) Kitagawa, T. (Cancer Inst., Tokyo, Japan), T. Yokochi and H. Sugano. *Int J Cancer* 10(2):368-381, 1972.

The appearance of serum α -fetoprotein and its relation to hepatocarcinogenesis were studied in four different strains of rats fed a diet containing 3-methyl-4-(dimethylamino)azobenzene (MDAB) or N-2-fluorenylacetamide (FAA). The appearance of α -fetoprotein, as determined by immunoelectrophoretic methods, was biphasic showing an early (third to fifth wk) and a late appearance (15th to 24th wk, during the development of large carcinomas). The frequency of early appearance depended on the age, sex, and strain, being highest in younger male animals of the Donyu strain. The lowest frequency of early α -fetoprotein occurrence was found in Sprague-Dawley and ACI rats. These early changes were paralleled histologically by the appearance of proliferative oval cells and small hepatocytes. There was a good correlation between serum α -fetoprotein levels and the intensity of oval cell proliferation. In general, MDAB was a much stronger carcinogen than FAA in producing early serum α -fetoprotein. With the appearance of hyperplastic nodules beginning in the sixth wk, serum α -fetoprotein fell to very low levels or disappeared. With the development of hepatic carcinomas, which were usually multiple, serum α -fetoprotein levels again increased. Most MDAB-induced tumors were of the mixed type and required a minimal diameter of 10 mm before serum α -fetoprotein could be detected. The FAA-induced tumors, which were primarily trabecular, were relatively weak α -fetoprotein producers and required a diameter of over 20 mm for fetoprotein synthesis. The degree of early α -fetoprotein production correlated with the frequency of development of carcinomas which produced high α -fetoprotein levels. However, the early appearance of serum α -fetoprotein was not necessary for the subsequent development of liver carcinomas.

- 5099 ELECTRONIC STRUCTURE AND CARCINOGENIC ACTIVITY OF 3,4-BENZOPYRENE AND 1,2-BENZOPYRENE. (Ger.) Popp, F. A. (Radiation Clin. U. Marburg, West Germany). *Z Naturforsch [B]* 27(7):850-863, 1972.

Differences in the properties of electronic structures between 3,4-benzpyrene (BP), and 1,2-benzpyrene were used to construct a possible model of the mechanism of chemical carcinogenesis. From a resonance analysis, the following statements emerged: The first stage of chemical carcinogenesis consists of resonance coupling of the carcinogen sender with the bioreceptor imprisoner, in which electric dipole oscillations are caught and imprisoned, thus apparently damaging the structure of the receptor. The carcinogen disturbs the structure of the bioreceptor by excitons of a higher energy. The receptors are the DNA and RNA bases in which the hydrogen bridges are disrupted. This mechanism affects the 3,4-BP release but not the 1,2-BP. The 3,4-BP has better acceptor as well as donor abilities than the 1,2-BP; the overlapping and free valence of atom 17 of 3,4-BP is more conducive to coupling with the receptor than the 1,2-BP in every possible relative position. The excitons can be led in every direction within the 3,4-BP molecule, but can only move in one direction in the 1,2-BP.

5100 ALTERATION IN THE DISTRIBUTION OF BASIC SOLUBLE RAT LIVER PROTEINS DURING AZO DYE CARCINOGENESIS. (E.) Louis, C. J. (Dept. Path., U. Melbourne, Australia) and J. M. Blunck. *Cancer Res* 31(12):2110-2115, 1972.

Antigens of *h* protein and azoproteins were prepared from cell sap of livers of normal rats and rats fed or injected with 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB). Antibodies to these antigens were induced in mice by injecting them with cell sap antigens i.p. Ascites from injected rats were tapped and γ -globulin fractions were isolated and labeled with fluorescein isothiocyanate (FITC); FITC-labeled anti-*h* and antiazoprotein antisera were used as histoserological stains for sections of livers of normal rats and rats fed or injected with 3'-MeDAB. Anti-*h* protein serum stained cytoplasm of normal liver cells; fluorescence staining was uniformly distributed throughout cytoplasm. Similar cytoplasmic staining with anti-*h* protein was seen in 3'-MeDAB-treated liver sections. Pretreatment of normal liver sections with unlabeled anti-*h* protein followed by FITC-labeled antiazoprotein inhibited cytoplasmic fluorescence. Normal rat livers were stained by antiazoprotein serum; staining was concentrated in nuclear and plasma membranes, and to a lesser degree in cytoplasm. FITC-labeled antiazoprotein stained only cytoplasm in 3'-MeDAB-treated cells. This cytoplasm staining was inhibited by pretreating liver sections with unlabeled antiazoprotein serum but not by pretreatment with anti-*h* protein. Neither serum stained 3'-MeDAB-induced hepatoma cells.

5101 ULTRASTRUCTURAL ASPECT OF LESIONS INDUCED IN MOUSE LUNG BY N-NITROSO-N-METHYLURETHANE: WITH AN ATTEMPT AT INTERPRETATION OF CRYSTALLINE CELLULAR INCLUSIONS. (Fr.) Pluot, M. (Fac. Med. Reims, France), C. Hopfner, J. J. Adnet and T. Caulet. *Z Krebsforsch* 77(4):279-291, 1972.

A morphological study of pulmonary tumors induced in

mice by N-nitroso-N-methylurethane (NMUR) is described. Nuclei in the area of the tumor, are described with reference to their shape, volume, chromatin, interchromatin granules, nucleoli and nuclear membrane. The mitochondria in the cytoplasm and microbodies in contact with them are also detailed, as well as the Golgi apparatus. In a large number of tumor cells there appear crystalline spindle-shaped formations which cling together longitudinally, and are thought to be lipoproteins. In the peritumoral areas, a dense collagenic substance is described, as well as crystalline formations. The presence of some peritumoral capillaries of a fenestrated type may indicate a bronchial origin. Almost all tumoral cells include numerous microvilli, and lamellar intramitochondrial bodies are described. The constitution of the crystalline inclusions is discussed together with their induction by chemicals. It is suggested that they are formed in the endoplasmic reticulum; they occur either free in the intercellular space or may be phagocytosed by the macrophages of the peritumoral areas. Macrophage-like cells phagocytosing these crystals are found within the body of the tumor; most of these cells were proven to be real macrophages and some were found to be atypical tumor cells.

5102 PURIFICATION AND PROPERTIES OF THE PRINCIPAL LIVER PROTEIN CONJUGATE OF A HEPATIC CARCINOGEN. (E.) Sorof, S. (Inst. Cancer Res., Philadelphia, Pa.), V. M. Kish and B. Sani. *Biochem Biophys Res Commun* 48(4):860-865, 1972.

Adult rats were fed diets containing 0.058% 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB) for 15-18 days. After 3'-Me-DAB feeding, the rats were killed and their livers perfused and homogenized to yield clear cytosol fractions. The main carcinogen-protein conjugate of rat liver cytosol was purified and characterized. This principal azocarcinogen-protein conjugate (h_2 -5S) was purified 204- to 286-fold compared to its concentration in whole liver. The isolated azoprotein was 88-91% pure according to gel electrophoresis. The subunit molecular wt of the azoprotein was 43,000 (minor component 28,000, trace component 38,000), indicating that the molecule (molecular wt 60,000-80,000) exists as a dimer. The subunits were apparently not disulfide-linked, since omission of β -mercaptoethanol before gel electrophoresis yielded protein of the same subunit size. The average subunit of the h_2 -5S azoprotein contained 0.7 mole of azo dye, equal to 1.4 moles dye/mole average protein (two subunits). The azoprotein was apparently not derived from liver arginase, and it differed from the previously isolated minor conjugate derived from liver protein.

5103 CARCINOGENICITY OF AZOXYMETHANE DEPENDENT ON AGE IN BD RATS. (E.) Druckrey, H. (Max Planck Inst. Immunobiol., Freiburg, West Germany) and A. Lange. *Fed Proc* 31(5):1482-1484, 1972.

Rats aged 1, 3, 10, 30 or 60 days were given single s.c. injections of 4, 6, 12, 20 or 40 mg/kg azoxyme-

thane; adult rats were given repeated weekly injections. All doses of azoxymethane were carcinogenic. Fourteen of 58 rats given azoxymethane at one day of age developed fatal malignant brain and nervous system tumors, mostly neurinomas of the trigeminal nerve. With increasing age at treatment, the yield of neurogenic malignant tumors decreased markedly. The yield of nephroblastomas was not dependent on the age of treated animals. Colonic and rectal adenocarcinomas were induced by a single dose of azoxymethane on the first day of life. Preliminary results suggest that with increasing age at treatment, the relative yield of intestinal tumors increases.

- 5104 CARCINOGENESIS IN TISSUE CULTURE. XVI. MALIGNANT TRANSFORMATION OF RAT CELLS BY N-METHYL-N'-NITRO-N-NITROSOGUANIDINE. (E.) Takii, M. (Fac. Med., Kyushu U., Fukuoka, Japan), R. Takaki and N. Okada. *Jap J Exp Med* 41(6):563-579, 1971.

Malignant transformation of thymus and lung cells from young rats was achieved in 15- and 25-day-old cultures given a single 2-hr exposure to 10 $\mu\text{g/ml}$ N-methyl-N'-nitro-N-nitrosoguanidine (NG) or seven 2-hr exposures to 1 $\mu\text{g/ml}$ NG. Loss of contact inhibition and a criss-cross arrangement of cells were observed two months after one exposure to 10 $\mu\text{g/ml}$ NG and 2 wk after the final exposure to 1 $\mu\text{g/ml}$ NG. In single-treated cells, morphological alterations and pleomorphism were seen by five months. Cultures receiving multiple treatments showed a considerable number of giant cells 2 wk after the last treatment. Cell proliferation rate in these cells increased but remained lower than that in untreated control cells. Rat thymus cells in 169-day-old cultures also underwent malignant transformation following seven exposures to 10 $\mu\text{g/ml}$ NG; however, no obvious changes occurred in the morphology of these cells. When NG-treated cells were inoculated s.c. into three syngeneic newborn rats, tumors developed in every case. Untreated cells produced no tumors. Cells transformed by a single NG treatment contained 68-83 chromosomes after 365 days of culture compared with 37-46 chromosomes in untreated cells. NG-transformed cells and control cells did not differ significantly in their resistance to the cytotoxic effect of NG. A higher colony-forming efficiency (CFE) was seen in soft agar for NG-transformed cells than for untreated cells, but the CFE of the transformed cells did not appear to correlate with tumorigenicity on implantation.

- 5105 MODIFICATION OF THE FLOW DICHROISM SPECTRUM OF RAT LIVER NUCLEAR DNA BY *IN VIVO* ALKYLATION WITH HEPATOCARCINOGENIC DIALKYLNITROSAMINES. (E.) Arcos, J. C. (U.S. Public Hlth. Service Hosp., New Orleans, La.), N. Venkatesan and M. F. Argus. *Gann* 62(6):523-533, 1971.

The differential flow dichroism (expressed as $\Delta\epsilon/M$) and the reduced dichroism ($\Delta\epsilon/\epsilon$) of DNA isolated from the livers of intact rats as well as of rats injected i.p. with dimethylnitrosamine (DMN) and diethylnitrosamine (DEN) were studied in 0.001, 0.01, and 0.1M NaCl (pH 7). The $\Delta\epsilon/M$ spectra of normal

liver DNA approximate is typical absorption spectrum and the increase of ionic strength has a strong hypochromic effect. Increase of ionic strength has, however, considerably less hypochromic effect of the $\Delta\epsilon/M$ of DMN-alkylated DNA and no effect on DEN-alkylated DNA. The $\Delta\epsilon/\epsilon$ of normal rat liver DNA increases about five-fold between 220 and 290 nm. The upward trend of the $\Delta\epsilon/\epsilon$ spectrum is interrupted by a peak at 250 nm (approximating the deoxyguanilic acid max. at pH 7) and a shoulder at 270-280 nm (approximating the highest absorption range of deoxycytidylic acid at pH 7). Increase of ionic strength brings about progressive lowering of the whole $\Delta\epsilon/\epsilon$ spectrum of normal DNA, but has little or no effect on the 250-nm peak and 270-280 nm shoulder. The $\Delta\epsilon/\epsilon$ spectra of the alkylated DNA's is appreciably lower in 0.001M NaCl than the $\Delta\epsilon/\epsilon$ of normal DNA, but the spectra change little with increase of the ionic strength. In contrast, unlike in normal DNA, the 250-nm peak of the alkylated DNA's progressively flattens by decreasing the ionic strength. The data suggest that at the alkylated G+C-rich segments the helix opens and "puffs" appear because of loss of hydrogen bonding. The "puffs", large at low ionic strength, are minimized by hydrophobic compression at high ionic strength.

- 5106 A STUDY ON POSSIBLE BLASTOMOGENIC EFFECT OF LUBRICATING OILS. (Rus.) Vasil'eva, N. N. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow), A. B. Linnik and A. K. Sgibnev. *Gig Tr Prof Zapol* 10:50-51, 1971.

The carcinogenicity of pentaerythrite ester oil (oil No. 1), diethylene glycol oil (oil No. 2), and a mixture of these two oils (No. 3) was studied using 218 hybrid mice (F_1 C57xCBA). Two drips of oil were applied on the previously depilated interscapular skin three times a week for one yr. The animals were studied for two yr. After two yr all surviving animals were sacrificed for study of the skin and the internal organs, which were paraffin-treated, formaldehyde-fixed and hematoxylin-eosin-stained. Application of the oil to the skin caused papilloma of the skin in only one case (oil No. 2). Lymphoreticulosarcoma was observed in six of 74 mice treated with oil No. 1 and in four of 70 treated with oil No. 3, while 315 control mice did not show any incidence of lymphoreticulosarcoma. However, the number of animals with tumors in all series of experiments did not exceed the number of control animals with tumors. Oil No. 2 (diethylene glycol) can be safely used as lubricating oil, while oil No. 1 (pentaerythrite ester oil) should be studied further in relation to its possible leukemia-inducing effect.

- 5107 MORPHOLOGY OF TUMORS OF THE NERVOUS SYSTEM PRODUCED BY ALKYLATION. (Ger.) Zülch, K. J. (Max-Planck Inst. Brain Res., Cologne, West Germany) and H. D. Mennel. *Zentralbl Neurochir* 32(5/6): 225-243, 1971.

A report is given on the morphology and localization of 1731 experimentally induced tumors of the brain, spinal cord, and peripheral nervous system. The tumors developed in rats, rabbits, or hamsters given chemical substances for which alkylation is assumed to be the common mode of action. Test results are classified according to substance applied and type of application, tumor type and incidence, number of test animals, number of tumors produced and their location. Iso- and polymorphous forms of tumors are distinguished according to a four degree scale: benign, semibenign, semimalignant, and malignant. Individual descriptions are given of glioma, ependymoma, neurinoma, sarcoma, hypophyseal adenoma, medulloepithelioma, esthesio-neuroepithelioma, and some rare tumors. The white matter was affected in 50% of the experimentally induced brain tumors, one-fifth of which were limited to the subependymal area. These were mainly small isomorphous gliomas. Twenty percent of all brain tumors occurred in the ventricular system. In the spinal cord, the preferred sites were the central canal or the area of the septum dorsale. Most tumors of the peripheral nervous system occurred in the trigeminal nerve. The implication of test results for the pathogenesis of tumors in man is discussed.

R. (Path. Inst. Med. Acad. Erfurt, East Germany). *Exp Pathol (Jena)* 6(3/4):158-166, 1972.

Tumor clones from dogs and rats in which central nervous system tumors were induced by methyl nitroso urea (MNU) were studied morphologically and cytogenetically in repeated cloning for purposes of characterization. The clones originated in the following primary tumors: clones PIE 9-1 and 9-2, a multiform glioblastoma induced in a dog by 20 mg/kg, (i.v.) at 4-week intervals, with a latency period of 426 days; and clone PIE 31-2, a gliosarcoma of the cerebrum, induced in a rat with a similar dose i.p. In the course of cloning, the individual clones developed from 20-40 cells/colony to a marked polymorphy. Giant cells with giant nuclei, or with smaller nuclei, were present with irregular numbers of nucleoli. There was a variable number of cell processes, which were more marked in clone PIE 31-2. Mitoses were confined mostly to mononuclear cells, generally unequal and often multipolar. Even long-term cultures did not reveal definite cell types. It is thus concluded that polymorphism occurs through cell fusions and multipolar mitoses. Analogous changes occurred during repeated *in vivo* transplantations.

5108 INDUCTION OF HEART TUMORS IN BD-RATS BY CONTINUOUS ORAL ADMINISTRATION OF THE CARCINOGEN 1-PYRIDYL-3,3-DIETHYL-TRIAZENE (PDET). (Ger.) Ivankovic, S. (Inst. Exp. Toxicol. Chemother. German Cancer Res. Ctr., Heidelberg, West Germany), H. Wohlenberg, H. D. Mennel and R. Preussmann. *Z Krebsforsch* 77(3):217-225, 1972.

5110 MORPHOLOGY OF TRANSPLACENTALLY INDUCED NEUROGENIC TUMORS IN SYRIAN HAMSTERS. (Ger.) Mennel, H. D. (Max Planck Inst. Brain Res., Cologne, West Germany) and K. J. Zülch. *Acta Neuropathol (Berl)* 21(3):194-203, 1972.

Fine tissue analysis of tumors induced by ethylnitrosourea (ENU) transplacentally in Syrian hamsters is presented. The ENU was injected i.v. on the 15th day of pregnancy in a dose of 30 mg/kg. The neonates were observed for neurological symptoms or indications of malnourishment when they were sacrificed and examined. Of 22 animals, 14 died with malignant tumors of the trigeminal, the peripheral subcutaneous or kidney types. In the 14 animals with tumors, there was a total of 16 tumors, five of which affected the trigeminal nerve or the Gasserian ganglion. These tumors appeared early and exhibited features typical of malignant neurinomas. Trigeminal tumors with marked regressive changes were also observed; such regressive changes are generally associated with peripheral tumors. With the onset of tumor growth, especially in the trigeminal and Gasserian ganglion, there was a direct increase of Schwann's cells between the boundaries of this nerve. The marked regressive changes appear to be a specific feature of the Syrian hamster species.

5111 POST- AND PRENATAL NERVOUS SYSTEM TUMOR INDUCTION WITH PHENYL-DIMETHYL-TRIAZENE IN THE RAT. (Ger.) Schneider, J. (Med. Acad. Erfurt, East Germany), R. Warzok and D. Schreiber. *Zentralbl Allg Pathol* 115:8-12, 1972.

Nervous system tumor induction by 1-phenyl-3,3-dimethyl-triazene (PDMT) was observed in two groups of Hauben rats: 44 young male and female rats

5109 *IN VITRO* BEHAVIOR OF CLONES OF GIANT CELL TUMORS EXPERIMENTALLY INDUCED IN THE CENTRAL NERVOUS SYSTEM OF DOG AND RAT. (Ger.) Thust,

given 10 mg/kg PDMT i.v., at biweekly intervals, as an oil emulsion in 10% ethanol (Group I); and 59 offspring from nine litters whose mothers had received 10 mg/kg PDMT on days 14, 16, 17, 22 or last day (23) of pregnancy (Group II). The last animal in Group I died after 755 days, and the sacrifice of Group II survivors was carried out after 980 days. Four out of the Group I animals developed cerebral tumors and five developed malignant extraneural tumors. A single i.v. injection of 10 mg/kg PDMT during the second half of pregnancy induced tumors of the central nervous system in eight of 59 offspring, and malignant tumors with predominantly newly differentiated lympho- and reticulosarcomas in 12 other offspring. The microcephalia observed in 20% of the offspring demonstrates that PDMT also exerts a teratogenic effect in the nervous system of rats. The results are compared with reports in the literature.

5112 KARYOLOGY OF 3-METHYLCHOLANTHRENE-INDUCED RHABDOMYOSARCOMAS. (It.) Basso, M. (Inst. Animal Biol. U. Padua, Italy). *Tumori* 58:107-120, 1972.

Three primary rhabdomyosarcomas, induced in adult female rats with a single dose of 3-methylcholanthrene (50 mg), were subjected to karyologic studies in an attempt to establish the effect of the neoplastic condition on the chromosomal setup of the rat. Monocellular tissue suspensions of the three tumors, referred to as S1, S2, and S3, were prepared by digestion with trypsin and seeded into an Eagle's medium containing 20% of horse serum. Metaphase block was achieved with colchicine 48-72 hr after culture initiation. The three sarcomas presented different numerical distributions of chromosomes: most of the S1 metaphases (65%) were subtetraploid with 67-70 chromosomes; the majority of the S2 metaphases were diploid with 39-47 chromosomes and only 25% were subtetraploid with 76-83 chromosomes; S3 presented hypertetraploid or even suboctoploid metaphases with 57-165 chromosomes. An increasing number of chromatid breaks and translocations leading to the formation of additional chromosomes, not occurring in the normal rat karyogram, as observed along with the increase in the number of chromosomes. The karyologic setup of the tumors corresponded to their histologic features, in that the polyploid S1 and S3 rhabdomyosarcomas were highly dedifferentiated, while the almost diploid S2 presented a well-distinguished muscular component. The occurrence of new chromosomes might, possibly, be associated with the initiation of the neoplastic process.

5113 INDUCTION OF LUNG CANCER IN GERM-FREE, SPECIFIC-PATHOGEN-FREE, AND INFECTED RATS BY N-NITROSEPTAMETHYLENEIMINE: ENHANCEMENT BY RESPIRATORY INFECTION. (E.) Schreiber, H. (Oak Ridge Natl. Lab., Tenn.), P. Nettesheim, W. Lijinsky, C. B. Richter and H. E. Walburg, Jr. *J Nat Cancer Inst* 49(4):1107-1114, 1972.

The effect of chronic respiratory infection on the development of lung cancer induced by N-nitrosoheptamethyleneimine was tested in rats. The nitrosamine was administered in drinking water for 22 wk to germ-free and specific-pathogen-free (SPF) rats and to rats with chronic murine pneumonia. All animals were killed two wk after the last treatment. The incidence of lung neoplasms was 17% in germfree males, 37% in SPF males, and 83% in infected males. An incidence of 90-100% was found among females in all 3 experimental groups. The results in males demonstrate that chronic respiratory infection can enhance the neoplastic response of the lungs to a systemic carcinogen. Possibly infection accelerates the growth of transformed cells by inducing vigorous repair processes. Alternatively, infection may increase the size of the susceptible cell population, alter the metabolism of the carcinogen, or suppress immunologic surveillance. The normal microbial flora did not appear implicated in the nitrosamine carcinogenesis. There was no significant difference in incidence of esophageal tumors among the three groups.

5114 INTERACTION OF URETHAN WITH MACROMOLECULES IN MALE AND FEMALE NEWBORN, ADULT, AND TUMOR-BEARING MICE. (E.) Chavan, B. G. (Cancer Res. Inst., Bombay, India) and S. V. Bhide. *J Nat Cancer Inst* 49(4):1019-1025, 1972.

Interactions of urethan with different macromolecules, such as DNA, RNA, and protein, from lung and liver tissues of adult, newborn, and tumor-bearing Swiss mice were studied. After tritiated urethan injection, more specific radioactivity was observed in lung DNA than in liver DNA of adult mice at 12 hr. Specific radioactivity in RNA and protein fractions from lung and liver tissues was similar. Study of mice treated with ^{14}C -urethan and sodium carbonate showed that radioactivity at 4 hr was due to binding, whereas at 12 hr the radioactivity was only partly due to binding. The time curve of radioactivity in DNA and RNA fractions of newborn mice treated with ^3H -urethan indicated that radioactivity was still present until 2 wk after urethan administration. Only the urethan-DNA interaction showed differential behavior in the tissues of tumor-bearing mice.

5115 A COMPARATIVE STUDY OF THE TUMORIGENIC ACTION OF URETHAN IN C_3H MICE AND *PEROMYSCUS LEUCOPUS*. (E.) Kisielski, W. E. (Argonne Natl. Lab., Ill.), E. Staffeldt and R. J. M. Fry. *Argonne Nat Lab Ann Report* 7870:47-48, 1971.

C_3H mice, aged 85 or 282 days, and *Peromyscus leucopus*, aged 18-20 months, were injected i.p. with 1.0 mg/kg ^{14}C -labeled urethan. Animals were killed at 4, 6, 24 and 48 hr postinjection and blood, liver, lung and thymus were extracted for ^{14}C contents. ^{14}C -labeled urethan appeared in equal concentrations in liver, lung and thymus of mice. Less than 1-2% of label was retained by mice after 24-48 hr. Urethan was taken up and cleared at the same rate in *P. leucopus* as in mice. There was no apparent difference in the catabolism of urethan in the two species. Therefore, the reported

lack of tumor production in *P. leucopus* exposed to urethan as compared with increased tumor incidence in exposed mice does not reflect species differences in urethan uptake and catabolism.

- 5116 ULTRASTRUCTURAL CHANGES PRODUCED BY THE CARCINOGEN, AFLATOXIN B₁, IN DIFFERENT TISSUES. (E.) Bauer, L. (Path. Inst., U. Erlangen-Nuremberg, West Germany), A. H. Tulusan and E. Müller. *Virchows Arch Zellpathol* 10(4):275-285, 1972.

Fresh water fish (*Brachydanio rerio*) and snails (*Planorbis corneus*) were exposed to aflatoxin B₁ in their aquarium water (2 ppm dilution). Ultrastructural changes in liver cells of fish and in epithelial cells from snails' tentacles were inspected. In fish exposed to aflatoxin B₁ for 24 hr, liver cell nucleoli were diminished in size and showed a compact spheroidal shape. Two zones of different densities were seen in modified nucleoli: a fibrillar zone and a granular zone. These changes were more pronounced in hepatic cells from fish exposed to aflatoxin B₁ for 48-72 hr. Similar changes were seen in nucleoli from snail cells. No neoplasms were observed in fish or snails nine months after acute exposure to aflatoxin B₁.

- 5117 MORPHOLOGIC CHANGES IN RAT LUNGS INDUCED BY INTRATRACHEAL INTRODUCTION OF CHRYSOTILE ASBESTOS ALONE AND WITH BENZ(a)PYRENE. (Rus.) Pylev, L. N. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow). *Vopr Onkol* 18(6):40-45, 1972.

Possible carcinogenic properties of asbestos were studied using mice. Ground chrysotile (2 mg) in 0.2 ml physiological solution was administered intratracheally to 61 hybrid mice for one month. A mixture of 2 mg ground chrysotile and 5 mg benzo(a)pyrene in 0.2 ml physiological solution was administered once to 35 mice. Benzo(a)pyrene (5 mg) was administered once to 28 mice. All mice died within 29 months. Early mortality was high in the group receiving the mixture of chrysotile and benzo(a)pyrene: 24 mice died within 1.5 months. Paraffin sections were made of lungs, liver, kidneys, and spleen of dead animals for histological and polariscopic studies. Inflammatory changes were most pronounced in the second group during 1.5 months, accompanied by interstitial pneumonia with sclerotic patches. Such changes were less evident in the third group, which received only benzo(a)pyrene. This group did not show sclerotic patches. The second group showed chronic productive interstitial pneumonia with parenchymal sclerosis. The asbestos grains were visible in polarized light in the lungs in both the first and second groups. Precancerous changes were most pronounced in animals of the second group, who showed hyperplasia and proliferation of the bronchial epithelium with dense cell metaplasia. Tumors of the lungs and pleura were found in 6/11 (54.5%) animals of the second group. Two of these mice had pleural mesotheliomas. Although there were precancerous changes in some animals, tumors were not seen in animals of the remaining two groups.

- 5118 THE RANGE OF EXTRANEURAL TUMORS, DEVELOPED IN RATS AFTER ADMINISTRATION OF N-METHYL-N-NITROSOUREA. (Ger.) Schreiber, D. (Med. Acad., Erfurt, East Germany), R. Warzok, P. Scholtze, J. Schneider, A. Lageman and H. Batka. *Zentralbl Allg Pathol* 115:48-61, 1972.

The distribution of extraneural tumors in 808 rats following administration of methyl nitrosourea is described. Intragastric, i.p. and i.v. routes were used as well as various dose levels: 10 and 25 mg/kg at two and four wk intervals, resp., for i.v. injection; and 10 and 20 mg/kg at two and four wk intervals, resp., for i.p. and intragastric administration. In some of the 12 experimental groups, the effects of hypoxia and hormonal disturbances were tested. The results showed 251 rats with simultaneous malignant extraneural and neural tumors, and 143 with malignant tumors only outside the nervous system. The highest induction of extraneural tumors was effected by the intragastric route of administration. Repeated i.v. injections of 25 mg/kg of the carcinogen produced a significantly higher incidence of extraneural tumors than the similarly administered 10 mg/kg dose. A significantly higher incidence of tumors was also seen in animals ovariectomized before the start of the experiments. The following locations of extraneural tumors are listed in order of preference: stomach, tongue, intestine, mesentery, pelvic organs and abdominal wall, cardiac muscle, hearing area, mediastinum, throat region, and kidneys. In the gastric tumors there was a predominance of cornified squamous epithelial carcinomas of the omasum. Species-dependent differences between rats and rabbits are indicated.

- 5119 HIGH YIELD OF HEPATIC TUMORS IN RATS BY CYCASIN. (E.) Fukunishi, R. (Kagoshima U. Sch. Med., Japan), S. Terashi, K. Watanabe and K. Kawaji. *Gann* 63:575-578, 1972.

Sprague-Dawley rats, aged 21 and 50 days, were given 10 mg/kg cycasin in drinking water daily for ten days. Hepatic tumors were induced in 80-90% of rats. Latent periods for tumor induction were 167-480 days for 21-day-old rats and 251-556 days for 50-day-old rats. Two kinds of liver tumor were seen: hepatoma and hepatic sarcoma. Hepatomas were slightly more common than hepatic sarcomas. In two animals, both tumor types occurred. A few kidney tumors were also induced in cycasin-fed rats.

- 5120 CYTOPHOTOMETRIC MEASUREMENTS OF DNA AND HISTONE PROTEIN CONTENT IN EXPERIMENTALLY INDUCED SKIN TUMORS OF THE RAT AND HAIRLESS MOUSE. PART II. (Ger.) Rohrbach, R. (Path. Inst., U. Freiburg i. Br., West Germany), M. Lau, C. Thomas and W. Sandritter. *Beitr Pathol* 146(2):111-121, 1972.

Skin tumors induced in rats and hairless mice by repeated i.v. and i.p. injections, resp., of diazoacetic-ester were examined cytophotometrically for DNA and histone protein content. Increases in both substances were closely correlated in all tumor cell populations. The Feulgen fast green quotient varied slightly between 0.95-1.31. Basal cell carcinomas fell into two groups histologically and cytophotometrically. Those consisting mainly of solid masses showed an euploid DNA distribution and only a 6.8-22.9% increase in DNA and histone protein, while a larger group of basal cell carcinomas with horny cysts, sebaceous gland cells, and spinal cells exhibited aneuploid stem lines and a 35-114% increase in DNA and histone protein. The biological behavior of the experimentally produced tumors is discussed in relation to human basal cell carcinomas.

5121 ARYL HYDROCARBON HYDROXYLASE INDUCTION IN HUMAN LEUKOCYTES. (E.) Busbee, D. L.

(U. Texas M. D. Anderson Hosp., Houston), C. R. Shaw and E. T. Cantrell. *Science* 178(4058):315-316, 1972.

A method for measuring aryl hydrocarbon hydroxylase (AHH) induction in normal human leukocytes is described. Leukocytes from healthy volunteers were incubated in the presence of phytohemagglutinin (PHA) for 72 hr. Addition of 3-methylcholanthrene (3MC, 0.75 mM) to the 72-hr cultures caused a fourfold increase in AHH activity. In the absence of PHA, 3MC stimulation of AHH activity did not occur.

5122 DIFFERENCES IN THE PATTERNS OF METHYLATION IN RAT LIVER RIBOSOMAL RIBONUCLEIC ACID AFTER REACTION *IN VIVO* WITH METHYL METHANESULPHONATE AND *NN*-DIMETHYLNITROSAMINE. (E.) O'Connor, P. J. (Paterson Labs., Manchester, England), M. J. Capps, A. W. Craig, P. D. Lawley and S. A. Shah. *Biochem J* 129(3):519-528, 1972.

Rats were given i.p. injections of ^{14}C -methyl methanesulphonate (50 mg/kg) or *NN*-dimethylnitrosamine (2 mg/kg). Three or five hr later, rats were killed, livers were removed, and rRNA was extracted from liver homogenates. This ^{14}C -methylated rRNA was subjected to enzymic digestion to nucleosides at pH 8, alkaline hydrolysis and conversion into nucleosides, or acid hydrolysis to bases. Methylation products of rRNA hydrolysates were analyzed by column chromatography on Dowex-50 (H^+ form) and Dowex-50 (NH_4^+ form). With both methylating agents the principal product of methylation was 7-methylguanine. Column chromatography of acid hydrolysates revealed differences in the methylation of other minor bases. Methyl methanesulphonate treatment produced more 1-methyl-adenine and 1-methylcytosine than treatment with *NN*-dimethylnitrosamine. In addition, methylation at the 0-6 position of guanine was not detected after methanesulphonate treatment, while 3-4% of the total methylation products were present as 0⁶-methylguanine after the reaction with *NN*-dimethylnitrosamine.

5123 CHANGES IN tRNA METHYLASE ACTIVITY OF RAT KIDNEY FOLLOWING ADMINISTRATION OF THE CARCINOGEN, DIMETHYLNITROSAMINE. (E.) Stewart, B. W. (Middlesex Hosp. Med. Sch., London, England) and A. E. Pegg. *Biochim Biophys Acta* 281(3):416-424, 1972.

Female rats which had been fed a protein-deficient diet for one wk were injected i.p. with 40 mg/kg dimethylnitrosamine. After another wk on the protein-deficient diet, rats were killed, kidneys were removed, and tRNA methylase activity was assayed in kidney extracts. Dimethylnitrosamine increased tRNA methylase in kidneys of rats fed a protein-deficient diet. At two days after dimethylnitrosamine, the rate of tRNA methylase in kidneys was about 85 pmoles methyl incorporated/mg protein/15 min, while the rate for control rats not given dimethylnitrosamine was about 40 pmoles methyl. At four days after carcinogen, tRNA methylase activity was 50% greater than in controls; by seven days, tRNA methylase was normal in dimethylnitrosamine-treated rats. However, increased tRNA methylase was also found in preparations from kidneys of rats treated with methylnitrosamine six months previously, two of which had overt kidney tumors.

5124 TRYPTOPHAN METABOLISM IN PATIENTS WITH BLADDER CANCER OF OCCUPATIONAL ETIOLOGY. (E.) Brown, R. R. (U. Wisconsin Med. Sch., Madison), G. H. Friedell and J. E. Leklem. *Am Ind Hyg Assoc J* 33(4):217-222, 1972.

Four groups of male subjects were given 2 g L-tryptophan and their excretion of urinary tryptophan metabolites was measured. The subjects included nine chemical workers with known exposure to bladder carcinogens (aromatic amines) and active bladder tumors (group I); ten men with similar exposures and with diagnosed bladder cancer, but who were tumor-free at the time of the study (group II); ten men exposed to carcinogens but with no sign of bladder tumors (group III); and ten unexposed healthy men (group IV). There were no statistically significant differences between the four groups in average basal, post-tryptophan or yield levels of any of the metabolites measured (kynurenine, acetylkynurenine, hydroxykynurenine, kynurenic acid, xanthurenic acid, indican, anthranilic acid glucuronide, o-aminohippuric acid) or creatinine. Kynurenine and hydroxykynurenine were slightly elevated in groups I and II relative to other groups. Two of eight subjects in group I and two of ten in group II showed two or more tryptophan metabolites in amounts greater than two standard deviations above normal. These subjects were regarded as having abnormal tryptophan metabolism.

5125 HEPATIC ADENYL CYCLASE: ALTERATIONS IN HORMONE RESPONSE DURING TREATMENT WITH A CHEMICAL CARCINOGEN. (E.) Christoffersen, T. (Inst. Pharmacol., U. Oslo, Norway), J. Morland, J.-B. Osnes and K. Elgjo. *Biochim Biophys Acta* 279(2):363-366, 1972

adenyl cyclase activity was assayed in liver particles from adult rats fed a diet containing 0.05% or 0.03% 2-acetylaminofluorene for four and ten wk, resp., and in particles from untreated rats. Adenyl cyclase response to adrenalin was of special interest. Adrenalin had only a slight effect on adenyl cyclase in liver particles from untreated rats. In livers of rats which had been given 2-acetylaminofluorene but which did not develop hepatocarcinomas, adenyl cyclase was markedly stimulated. The degree of adenyl cyclase stimulation by adrenalin over basal enzyme levels in liver particles from rats fed 2-acetylaminofluorene was similar to that in newborn rats. Adenyl cyclase from 2-acetylaminofluorene-fed rats which did develop tumors showed only a slight increase in response to adrenalin; however, basal adenyl cyclase levels in hepatocarcinoma-bearing, carcinogen-fed rats were increased.

26 CARCINOGEN-INDUCED tRNA METHYLASE ACTIVITY IN YEAST CELLS. (E.) Hancock, R. L. Div. Med. Biochem., U. Calgary, Alberta, Canada. *Archiv Biochem Biophys* 281(3):472-475, 1972.

Yeast cell extracts were cultivated with or without 100 µg of DL-ethionine, a hepatocarcinogen for mice. The tRNA methylase activity of yeast extracts as affected by ethionine was measured. Ethionine increased tRNA methylase in yeast cell extracts, while noncarcinogenic DL-methionine did not. Di-2-ethylaminoazobenzene also increased tRNA in yeast cell extracts, while noncarcinogenic aminoazobenzene did not.

27 INTRACELLULAR BINDING OF PHENOBARBITAL IN RAT LIVER. (E.) Peraino, C. (Argonne Natl. Lab., Ill.) and W. E. Kisielski. *Argonne Natl. Lab. Ann Report* 7870:45, 1971.

Rats were injected i.p. with 100 µCi ¹⁴C-phenobarbital. Twenty-four hr later, livers were removed and fractionated into nuclei, mitochondria, microsomes and supernatant. Labeled phenobarbital was found in nuclear, mitochondrial or microsomal fractions. Labeled phenobarbital was, however, found in cell sap, indicating that it bound strongly to soluble macromolecules, probably proteins.

28 METHYLAZOXYMETHANOL ACETATE: INDUCTION OF TUMORS AND EARLY EFFECTS ON RNA SYNTHESIS. (E.) Zedeck, M. S. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), S. S. Sternberg, J. McGowan and R. W. Poynter. *Fed Proc* 31(5):1485-1492, 1972.

A single i.v. injection of 35 mg/kg methylazoxymethanol acetate (MAM acetate) induced 22 cancers in 26 treated rats within 5-12 months. The cancers developed in the large and small intestines, liver and kidney. Fifteen rats had benign tumors, 7 of which were hyperplastic nodules of the liver. Hepatic structural alterations were seen as early

as 15 min after MAM acetate injection. DNA, RNA and protein synthesis were inhibited in liver one to three hr after treatment. Pathological effects of MAM acetate, including decreased cytoplasmic basophilia in hepatocytes, were noted as early as six hr after injection. Inhibition of RNA synthesis in isolated liver cell nuclei of rats given MAM acetate was confirmed in studies of UTP-5-³H uptake by these cells. Inhibition of UTP-5-³H uptake was dependent on the dose of MAM acetate and increased with time after MAM acetate. MAM acetate did not affect either RNA synthesis in kidney cell nuclei or orotic acid uptake into nucleolar RNA.

5129 PROLACTIN DEPENDENCE IN HUMAN BREAST CANCERS. (E.) Salih, H. (Westminster Hosp., London, England), H. Flax, W. Brander and J. R. Hobbs. *Lancet* 2(7787):1103-1105, 1972.

Biopsy tissues from 50 breast cancer patients were cultured with sheep prolactin, 17 β-estradiol and testosterone and the prolactin-dependence of the dehydrogenase activity of the pentose shunt was observed. Comparison biopsy tissues from the breast cancers were not cultured with added hormones. Cancer tissues from 16 patients showed higher dehydrogenase levels with prolactin added at 220 mU/ml. Four cancer specimens even showed increased dehydrogenase when prolactin was added at 22 mU/ml. Of the remaining 34 breast cancer specimens, 12% showed only estrogen dependence and 2% only androgen dependence. Fifty-four percent of the specimens were apparently not hormone-dependent at all.

5130 THE EFFECT OF CIGARETTE-SMOKE CONDENSATE ON THE *IN VITRO* FIXATION OF BENZO(a)PYRENE ON DNA. (E.) Alexandrov, K. (Inst. Sci. Res. Cancer, Villejuif, France) and C. Frayssinet. *Experientia* 28(8):932-933, 1972.

Male rats were injected i.p. with 3-methylcholanthrene (MC, 20 mg/kg/rat/day for two days) or cigarette smoke condensate (20 mg/kg). Liver microsomes were isolated and the bonding of benzo(a)pyrene (B(a)P) and/or its metabolites to microsomal DNA was observed. Both MC and cigarette smoke condensate facilitated bonding of B(a)P-³H and DNA. In microsomes from rats given neither MC nor smoke condensate, bonding of B(a)P-³H to DNA proceeded at a rate of 3.2 µM B(a)P-³H/µmoles P-DNA, while rates for rats given MC and smoke condensate were 23.0 and 22.0 µM B(a)P-³H/µmoles P-DNA, resp. Smoke condensates added to B(a)P-³H-DNA incubation mixtures *in vitro* inhibited fixation of B(a)P-³H to DNA. Metabolites of B(a)P-³H were fixed to complexes between DNA and smoke condensate metabolites less readily than to DNA itself.

5131 CYTOSKELETON ALTERATIONS IN CELLS OF RAT HEPATOMAS INDUCED BY 4-DIMETHYLAMINO-

AZO BENZENE. (E.) Briere, N. (U. Hosp. Ctr., Sherbrooke, Quebec, Canada). *J Nat Cancer Inst* 48(2):441-449, 1972.

Male Wistar rats were fed a low-protein diet containing 0.06% 4-dimethylaminoazobenzene (DAB). Animals were sacrificed at 30-day intervals during a 210-day feeding period. Histologic sections of liver containing preneoplastic foci and hepatomas were studied. Cytoplasmic RNA in these cell populations stained intensely with toluidine blue, and this phenomenon was used to identify them. The staining technique [tannic acid-phosphomolybdc acid-amido black (TPA)] that permits observation with the light microscope of cell web (cytoplasmic tonofibrils), terminal bars, and desmosomes was used to determine whether the hyperbasophilic cells were characterized by any modifications in cell web elements and other TPA-positive components. In normal hepatocytes and those surrounding the hyperbasophilic areas, the cell web was complete, extending all around the cells, and desmosomes were always present near the bile canaliculi. In preneoplastic and tumor cells, cytoskeleton and desmosomes were much reduced, absent, or too scanty to be observed. Moreover, cytoplasmic background (probably proteins) in surrounding tissue stained intensely with TPA, whereas hyperbasophilic cells were negative or weakly positive. RNA extracted by RNase did not alter significantly protein stainability, suggesting that those proteins were not masked by the RNA responsible for hyperbasophilia, but were present in small concentrations or were absent from cancer cells. These results indicated that important alterations in TPA-positive materials, especially the cytoskeleton and cellular attachment sites, are associated with the phenomenon of hyperbasophilia and neoplastic transformation.

5132 INDUCTION OF INTERSTITIAL CELL TUMORS BY CADMIUM CHLORIDE IN ALBINO RATS. (Ger.) Knorre, D. (St. George District Hosp., Leipzig, East Germany). *Arch Geschwulstforsch* 38(3-4):257-263, 1971.

The development of interstitial cell tumors (ICTs) was studied in 104 mature male rats given a single s.c. injection of 0.003 mM cadmium chloride/100g body weight. Within 48 hr, total necrosis of the testes occurred. Among 43 rats observed for 157-698 days postinjection, 36 developed ICTs. The ICTs were uni- or bilateral, and were often hemorrhagic. In most cases, the ICTs were only discovered histologically as subcapsular tumors, and in the same area where regeneration of interstitial tissue was initiated. In the large ICTs, small and dark-celled areas which alternated with light cells of a hypernephroid type; in the small ICTs, the cells were more compact and smaller. Metastases occurred in only one case. The biological evaluation of ICTs is predominantly subject to the length of time required for their development; the first ICT was not discovered until 355 days postinjection, while development of the two largest tumors took 580 days.

5133 EFFECT OF ENZYME INDUCTION ON THE METABOLISM OF BENZO(a)PYRENE AND 3'-METHYL-4-MONOMETHYLAMINOAZOBENZENE IN THE PREGNANT AND FETAL RAT. (E.) Welch, R. M. (Burroughs Wellcome Co., Research Triangle Park, N.C.), B. Gommi, A. P. Alvares and A. H. Conney. *Cancer Res* 32(5):973-978, 1972.

The effect of polycyclic hydrocarbons on the metabolism of benzo(a)pyrene (BP) and 3'-methyl-4-monomethylaminoazobenzene (3-m-MAB) in maternal and fetal rat liver was studied. Sprague-Dawley rats, pregnant 14-19 days, were treated with a single p.o. dose of 3-methylcholanthrene (3-MC), 60mg/kg, and killed 24 hr later. Microsomal preparations prepared from homogenates of maternal liver, placentas and fetal livers were tested for BP hydroxylase and 3-m-MAB *N*-demethylase activities using BP and 3-m-MAB resp. as substrates. 3-MC stimulated both BP and 3-m-MAB *N*-demethylase activity in maternal liver (13- to 15-fold and two-fold, resp.) and fetal liver (30-fold and two- to three-fold, resp.). Control animals which had received a p.o. placebo and 16-day pregnant rats treated with phenobarbital (50 mg/kg/day p.o. for three days) showed no BP hydroxylase activity in fetal liver homogenate. The effect of 3-MC and phenobarbital on induction of mixed-function oxidases in liver microsomes of 16-day pregnant rats was analyzed by observing increases in microsomal hemoprotein concentration as measured by the change in absorbance at 450 or 455 nm, when carbon monoxide or ethyl isocyanide was added as ligand to reduced liver microsomes. 3-MC and phenobarbital increased the microsomal hemoprotein concentration in maternal liver. 3-MC also increased hemoprotein concentration in fetal liver microsomes. 3-MC increased the ratio of the peak at 455 nm to the peak at 430 nm and shifted by two nm the maximum absorption of the 450 nm peak to a shorter wavelength in both maternal and liver microsomes, thus indicating a qualitative alteration of the microsomal hemoproteins. Phenobarbital had no effect on hemoprotein concentration in fetal liver microsomes. Several polycyclic hydrocarbons found in the environment and in cigarette smoke increased metabolism of BP and 3-m-MAB by fetal rat liver. Dibenz(a,h)anthracene and BP were the most potent stimulators (70- and 100-fold, resp.), but benz(a)anthracene (60-fold) and chrysene (30-fold) also increased enzyme activity. Anthracene had little or no effect. Maternal liver and placenta BP hydroxylase activity were ten to 20 times more sensitive to induction by BP (0.5 to 1.0 mg/kg/day for three day) than was fetal liver enzyme. Pretreatment of 16-day pregnant rats with nonradioactive BP (20 mg p.o. for three day) followed 24 hr later by p.o. administration of BP-³H showed that enzyme induction increased the ratio of BP-³H metabolites to BP-³H by 84-, 19- and 185-fold in the fetus, placenta and maternal lung, resp.

5134 PHENACETIN ABUSE AND CARCINOMA OF THE PELVIS. (Ger.) Grob, H. U. (Distr. Hosp. St. Gallen, Switzerland). *Helv Chir Acta* 38(5/6):537-539, 1972.

The carcinogenic effect of phenacetin is described. In a study of 20 patients with pelvic tumors, five were found to have used phenacetin to excess, and

these patients were definitely younger than the others. Two cases of pelvic carcinoma are described, both of these patients having ingested two to three pills of phenacetin/day for more than 18 years. The survival chances of patients with renal damage due to phenacetin have improved with modern methods of nephrology, but the incidence of pelvic carcinoma has increased comparatively. Since a cure for pelvic carcinoma is unknown, prophylactic measures must be taken in dealing with exogenous carcinogens.

5135 TUMORS, DEVELOPED AFTER I.P. INJECTION OF FIBER-LIKE DUSTS, IN THE RAT. (Ger.)

Pott, E. (Air Hyg. Silicosis Res. Med. Inst., U. Düsseldorf, West Germany) and K. H. Friedrichs. *Naturwissenschaften* 59(7):318, 1972.

To determine whether the tumor-inducing effects of asbestos are due to its physicochemical properties or to its fibrous consistency, a study was conducted in rats using various dust particles of a fibrous consistency or of some other form. The results of i.p. injections of 25 mg of each substance up to four times in one week showed that tumors were induced in animals receiving chrysotile, nemalite and glass fiber. These chemicals resemble each other in form but not chemically. Other substances, resembling chrysotile chemically but which are granular or foliar in form, did not lead to tumor formation within 530 days. Even nemalite, the chemical suspected of carcinogenic effects, did not induce tumors. It is thus possible that the inhalation of other fibrous dusts, particularly those of glass, leads to tumor formation.

5136 LEUKEMIA AND MAMMARY TUMOR IN RATS ADMINISTERED N-NITROSOBUTYLUREA. (E.) Hosokawa, M.

(Hokkaido U. Sch. Med., Japan), E. Gotohda and H. Kobayashi. *Gann* 62(6):557-559, 1971.

Rats were divided into four groups for administration of N-nitrosobutylurea in drinking water, as follows: female rats aged 1.5 months given 480 mg N-nitrosobutylurea for 120 days (A); females aged two months given 600 mg for 140 days (B); females aged three months given 720 mg for 180 days (C); and males treated as in (C), (D). Leukemia developed in 15% of rats in group A, in 53.6% of rats in group B, in 64.3% of rats in group C and 88.8% of rats in group D. Mammary tumors were observed in all group A rats, in 75% of group B rats, in ten of 14 group C rats and in no group D rats. The mean latent period for leukemia in all groups was 33 wk, while that for mammary tumor was 25 wk. Both leukemia and mammary tumors were found in individuals in groups A, B and C.

5137 THE KINETICS OF DECOMPOSITION OF N-ALKYL DERIVATIVES OF NITROSOGUANIDINE. (E.)

Haga, J. J. (Chem. Dept., North Texas State U., Denton), B. R. Russell and J. F. Chapel. *Cancer Res* 32:2085, 1972.

The kinetics of formation of the active alkylating species of N-methyl-, N-propyl-, N-ethyl- and N-butyl-N'-nitrosoguanidine were studied by scanning the spectra of the compounds in Tris and sodium phosphate buffers. The rate of decomposition of the N-methyl-, N-ethyl and N-propyl derivatives was found to be first order and to vary as a function of the increasing carbon number in the alkyl portion of the molecule. In addition, the decomposition rate was pH-dependent for all compounds except N-ethyl-N'-nitrosoguanidine. Because of its insolubility, no kinetic data were obtained for the N-butyl derivative.

5138 REACTION OF NITROSOUREAS WITH POLYCYTIDYLATE TEMPLATES FOR RIBONUCLEIC ACID

POLYMERASE. (E.) Ludlum, D. B. (U. Maryland Sch. Med., Baltimore) and P. N. Magee. *Biochem J* 128(3):729-731, 1972.

Samples of the polycytidylate template (poly(C)) were treated with N-methyl- or N-ethyl-N-nitrosourea and reacted with RNA polymerase. In the presence of methyl-nitrosourea-treated poly(C), GMP incorporation in the RNA polymerase reaction was reduced to 10% of its level in reactions with untreated poly(C). A significant misincorporation of UMP in the reaction was also seen with nitrosourea-treated poly(C). The substitution of cytosine by reaction with the carcinogens may have caused a misreading of the template by RNA polymerase.

5139 INHIBITION OF DNA REPAIR BY COCARCINOGENS.

(E.) Gaudin, D. (U. Alabama Sch. Med., Birmingham), R. S. Gregg and K. L. Yielding. *Biochem Biophys Res Commun* 48(4):945-949, 1972.

³H-thymidine-labeled normal human lymphocytes were exposed to UV radiation and mixed with hydroxyurea. DNA repair synthesis in this system was observed as uptake of ³H-thymidine by lymphocytes in the presence of three cocarcinogens: anthralin, 12-O-tetradecanoyl-phorbol-13-acetate and the neutral fraction from cigarette smoke condensate. All three agents were potent inhibitors of UV-stimulated DNA repair synthesis. At concentrations of 2.5×10^{-5} M, anthralin reduced DNA repair synthesis (measured as ³H-thymidine uptake) to <10% of that in lymphocytes not treated with cocarcinogens, while the phorbol ester reduced DNA repair synthesis to about 50% of normal at the same concentration. The neutral fraction of cigarette smoke, at a 0.01% dilution, reduced DNA repair synthesis to 50% of control.

5140 MOLECULAR ORBIT COMPUTATIONS ON 3,4-BENZPYRENE AND 1,2-BENZPYRENE PROVIDE A MODEL FOR THE

INTERPRETATION OF CHEMICAL CARCINOGENESIS. (Ger.) Popp, F. A. (Rad. Clin. U. Marburg/Lahn, West Germany). *Z Naturforsch [B]* 27(6):731, 1972.

A comparison of the differences in electronic structure between 3,4-benzpyrene (BP) and 1,2-benzpyrene by means of a semiempirical molecular orbit computation is presented. 3,4-BP manifests the first, energetically lowest pi-electron stimulus at 3.14 eV, and the second at 3.29 eV. With 1,2-BP, the stimulus energy is 3.54 eV for both the lowest and second-lowest stimuli. This is due to a superposition of the two configurations, whereas the higher stimulus of 3.74 eV represents a single configuration. The condition of the bipolar structures in a charge-transfer complex explains the different actions of the two substances. A disturbance in the H-bridge of 3,4-BP and the interaction with DNA or RNA bases are presumed to be the first steps in its carcinogenic effect.

- 5141 CARCINOGENIC ACTIVITY OF 5-HYDROXY-3,4-BENZOPYRENE. (E.) Nagata, C. (Nat'l. Cancer Ctr. Res. Inst., Tokyo, Japan), Y. Tagashira, M. Inomata and M. Kodama. *Gann* 62(5):419-421, 1971.

Male ddN mice were injected s.c. or intracutaneously with 0.3 mg or 0.06 mg 5-hydroxy-3,4-benzopyrene dissolved in benzene. One of 30 mice treated s.c. and one of 10 treated intracutaneously developed fibrosarcomas at the injection site. It had been shown previously that 7 mg 5-hydroxy-3,4-benzopyrene administered as crystals moistened with glycerol were not carcinogenic. The significance of solvents in hydrocarbon carcinogenesis is discussed.

- 5142 SKIN CARCINOGENESIS TESTS OF HYDROGENATED DERIVATIVES OF ANTHANTHRENE AND OTHER POLYNUCLEAR HYDROCARBONS. (E.) Lijinsky, W. (Eppley Inst., Omaha, Nebr.) and H. Garcia. *Z Krebsforsch* 77(3):226-230, 1972.

Anthanthrene, two of its derivatives and two derivatives of benz(a)anthracene were applied topically to Swiss mice for 50-75 wk. No tumors appeared in mice given anthanthrene, 4,5-dihydroanthanthrene or 1,2,3,7,8,9-hexahydroanthanthrene in amounts of 43, 39 and 36 µg, resp., twice a wk. However, 5,6-dihydro-7,12-dimethylbenz(a)anthracene (32 µg) caused squamous cell papillomas and squamous cell carcinomas in 50% of mice and 6,7,8,9,10,12b-hexahydro-3-methylcholanthrene (35 µg) caused squamous tumors in 67% of mice.

- 5143 SENSITIVITY OF REPAIR-DEFICIENT MUTANTS AND SIMILAR MUTANTS TO 4-NITROQUINOLINE 1-OXIDE, 4-NITROPYRIDINE 1-OXIDE, AND THEIR DERIVATIVES. (E.) Nagao, M. (Nat'l. Cancer Res. Inst., Tokyo, Japan) and T. Sugimura. *Cancer Res* 32(11):2369-2374, 1972.

The chemical carcinogens 4-nitroquinoline 1-oxide (4NQO) and 4-nitropyridine 1-oxide (4NPO), and their carcinogenic or noncarcinogenic derivatives, were tested by a slight modification of the rapid screening method for mutagens and carcinogens

described by Slater, Anderson, and Rosenkranz. *N*-Methyl-*N'*-nitro-*N*-nitrosoguanidine and methylmethanesulfonate were also tested. 4NQO, 4-hydroxyaminoquinoline 1-oxide, 3-methyl-4-nitropyridine 1-oxide, and 2,3-dimethyl-4-nitropyridine 1-oxide caused wider growth-inhibiting zones with mutants of *Escherichia coli*, such as the DNA polymerase I-deficient mutant, *polA1*, and the recombination-deficient mutants, *recA13* and *recB21*, than with the wild strain. These compounds also caused wider growth-inhibiting zones with ultraviolet-sensitive mutants of *Saccharomyces cerevisiae* and *Bacillus subtilis* than with the corresponding wild types. 4NPO, *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) and methylmethanesulfonate (MMS) caused wider growth inhibition zones with the *polA1*, *recA13*, and *recB21* mutants of *E. coli* than with the wild strain but similar zones with UV-sensitive mutants of *S. cerevisiae* and *B. subtilis* and the wild strains. The results indicate that different mechanisms are involved in repair of DNA damaged by ultraviolet irradiation or 4NQO and its derivatives on the one hand and by 4NPO, MNNG, or MMS on the other.

- 5144 CARCINOGENIC ACTION OF A SINGLE SUBCUTANEOUS ADMINISTRATION OF *n*-BUTYL-NITROSOUREA TO NEWBORN RATS: A SIMPLE MODEL FOR NEURO-ONCOLOGICAL STUDIES. (Ger.) Zeller, W. J. (Inst. Exp. Toxicol. Chemother., Heidelberg, West Germany) and S. Ivankovic. *Z Neurol* 202:121-127, 1972.

The production of malignant neurogenic tumors in the central and in the peripheral nervous systems by a single s.c. injection of 120 mg/kg of *n*-butyl-nitrosourea (BNU) in newborn rats is reported. Out of a total of 25 rats, 17 developed a total of 29 tumors, located in the cerebellum, cerebrum, trigeminal, cauda equina, spinal column, and various adjacent areas. The mean induction time was about 290 days. It is submitted that the organotropic action of a carcinogen is not only dependent on the chemical structure, but also on type of administration, dosage, and conditions of development of the biological receptors. The method is recommended for the study of neurogenic tumors.

- 5145 INHIBITION OF CARCINOGENIC AND TOXIC EFFECT OF DIETHYLNITROSAMINE ON RAT LIVER. (Ger.) Weissberg, M. (Inst. Cancer Res. U. Vienna, Austria). *Experientia* 28(6):682-683, 1972.

Experimental evidence is presented that i.p. injections of homologous thymus tissue in rats will protect the animals against toxic and carcinogenic effects of diethylnitrosamine (DNA). The study was conducted in 33 male Sprague Wistar rats who were injected i.p. with whole thymus (in physiological saline) taken from animals of the same strain; three such injections were effected at the rate of one/wk. One wk after the last thymus injection, the experimental animals, as well as a group of untreated controls, were given 400 mg DNA/kg body wt, in their drinking water. The experimental period ended when each rat (weight 150 g) had consumed 60 mg DNA. One month after the end

of the experimental period (and at various intervals following that), the rats were sacrificed and the liver was examined. The untreated controls revealed the presence of 14 carcinomas (out of 30 animals), whereas no carcinomas were found in the experimental animals. The extent of degeneration was marked in the controls and very slight in the treated animals. The study also demonstrated that toxic liver degeneration results from DENA (without protection by thymus) many months after the carcinogen was administered and is independent of time and dosage.

- 5146 CANCER INDUCING EFFECT OF N-NITROSOMETHYLUREA AFTER ADMINISTRATION OF HORMONAL CONTRACEPTIVES. (Ger.) Thomas, C. (Path. Inst. Ludwig Aschoff House, Freiburg i. Br., Germany), H. Rogg and J. Bucheler. *Beitr Pathol* 146(4):332-338, 1972.

The organotropic effect of N-nitrosomethylurea (NMU) was investigated with respect to changes by hormone contraceptives. Experiments were conducted in female Wistar rats who were divided into three groups of 40 rats each; all groups were given 40 mg NMU/kg. The control group was given NMU for three consecutive days; the experimental groups, in addition to the NMU, received an aqueous suspension of 0.0075 mg mestranol and 0.25 mg lynestrenol per day for 30 days, prior to or after NMU administration. Numerous tumors developed in control animals and animals given the hormone contraceptives after NMU treatment. Tumor production was significantly decreased in the group receiving the hormone contraceptives before NMU; a decrease in nephroblastomas was particularly evident. It was concluded that hormonal contraceptives do not directly induce cancer. No particular organotropic effect was manifested, particularly with respect to mammary or uterine tumors.

- 5147 A RESTATEMENT OF THE THEORY OF REGIONS K AND L IN RELATION TO THE MOLECULAR MECHANISMS OF ACTION OF CHEMICAL CARCINOGENESIS. (Fr.) Shou-Sin Sung, M. (CNRS, Essonne, France). *C R Acad Sci [D] (Paris)* 275(12):1307-1310, 1972.

An attempt to combine 11 aromatic nonalternating polycyclic hydrocarbons with 62 previously analyzed alternating homologs, is presented. The 11 hydrocarbons are shown in a table wherein the simple and complex indices of the K and L positions are calculated and the carcinogenic activity estimated. In a histogram of the distribution of energies of ortho-localization associated with 73 aromatic hydrocarbons (both alternating and nonalternating), the 11 hydrocarbons of this study are included. By this means the addition of nonalternating hydrocarbons is seen to differ from the alternating ones in the histogram. Experimental proof of the fixation of the carcinogenic hydrocarbons to biomacromolecules in the K region of the molecule was recently obtained in connection with fluorescent spectra of a mouse skin extract to which benzo(a)pyrene was applied. It is concluded that the experimental facts to date are too

few, and at times too contradictory, to attempt a statistical analysis dealing with a total of 62 molecules.

- 5148 THE CONTAMINATION OF FOOD WITH CARCINOGENIC HYDROCARBONS THROUGH TECHNOLOGICAL AND PREPARATIVE PROCESSES. (Ger.) Fritz, W. (Central Inst. Nutr., Berlin, West Germany). *Arch Geschwulstforsch* 40(1):81-90, 1972.

In consideration of the unexplained etiology of gastric cancer, the formation of carcinogenic hydrocarbons in cooking of food was investigated. In the roasting procedure of coffee beans, there are as a rule slight amounts of benzo(a)pyrene, also found in burnt bread crust and burnt biscuits. Under proper conditions of heating, such carcinogenic substances are negligible. Malt coffee roasted in contact with flue gas contained significant quantities of carcinogenic hydrocarbons, including benzo(a)pyrene, benzofluoranthene, indenopyrene and other polyaromatic substances. Similar contamination of smoked (or grilled) meats or fish is possible, depending on the processing. Contamination of cereals is effected by smoke-drying; systematic studies revealed that smoke-drying with technical fuel gas, such as city gas, was not associated with food contamination, whereas smoke-drying with gases emanating from diesel oil or heating oil, caused an increase in polyaromatic content. Ways to avoid contamination of foods with carcinogenic hydrocarbons during processing and cooking are discussed.

- 5149 EFFECT OF AGE AT TREATMENT AND DOSE OF 3-METHYLCHOLANTHRENE ON DEVELOPMENT OF LEUKEMIA AND SARCOMA IN AKR MICE. (E.) Whitmire, C. E. (Microbiol. Assoc., Inc., Bethesda, Md.), R. A. Salerno, V. A. Merold and L. S. Rabstein. *J Nat Cancer Inst* 49(5):1411-1415, 1972.

Several previous studies suggested a mutual exclusion between spontaneous leukemia and sarcoma induced in AKR mice by 3-methylcholanthrene (MCA). The results presented here indicate that this apparent exclusion was a function of the latency periods for spontaneous leukemia and MCA-induced sarcoma development. Leukemia occurred at about 32 wk of age and the latency period was unaffected by MCA treatment except in newborn animals. Sarcoma (independent of age of mice at MCA treatment) developed about 24 wk after treatment with 150 µg MCA, about 19 wk after 300 µg MCA, and about 17 wk after 450-500 µg MCA. When MCA was given at an age so that the latency period for sarcoma induction coincided with the chronologic age for leukemia development, leukemia and induced sarcoma were often found in the same animal.

- 5150 SELECTIVE INHIBITION OF NUCLEOPLASMIC RAT LIVER DNA-DEPENDENT RNA POLYMERASE BY AFLATOXIN B₁. (E.) Saunders, F. C. (Dept. Med., U. Washington, Seattle), E. A. Barker and E. A. Smuckler. *Cancer Res* 32(11):2487-2494, 1972.

Aflatoxin B₁, a potent hepatocarcinogen, causes rapid but reversible *in vivo* inhibition of DNA-dependent RNA polymerase in isolated nuclei. This study was designed to determine whether the consequent decrease of RNA formation occurs as a result of direct alteration of RNA polymerase. Aflatoxin B₁, 1 mg/kg body wt, was administered i.p. to male rats; nuclei were isolated from liver homogenates at various times up to 24 hr thereafter. RNA polymerase was solubilized by sonic disruption, concentrated, and dialyzed. Some preparations were further purified by fractionation with diethylaminoethyl Sephadex chromatography. Methods were selected to measure nucleoplasmic or nucleolar RNA polymerase in intact nuclei and in crude solubilized or fractionated preparations with exogenous template (denatured calf thymus DNA). Nucleoplasmic enzyme activity of all three preparations was inhibited to 40% of control values at two through nine hr after aflatoxin administration, but it returned to control values at 24 hr. Fractionated nucleolar polymerase activity two and 24 hr after toxin administration was not significantly different from control values. Addition of aflatoxin B₁ *in vitro* to nuclei and crude solubilized polymerase did not produce altered nucleotide incorporation. Aflatoxin B₁ *in vivo* appears directly to alter nucleoplasmic rat liver DNA-dependent RNA polymerase function. In the dose selected for this study, aflatoxin impairs nucleolar RNA polymerase much less, if at all. The failure of direct addition of aflatoxin B₁ to alter ³H-labeled uridine 5'-triphosphate incorporation *in vitro* provides further support to the theory that it is altered metabolically to a toxic form.

- 5151 PARTICIPATION OF SOLUBLE INORGANIC PYROPHOSPHATASE IN CANCERATION (RAT LIVER FOLLOWING DIETHYLNITROSAMINE AND CCl₄). (Ger.) Kittlick, P.-D. (Path. Inst. Friedrich-Schiller U., Jena, East Germany), H. Büttner and W. Klemm. *Exp Pathol (Jena)* 6(5/6):248-256, 1972.

The effect of changes in Mg⁺⁺ concentration on the activity of soluble inorganic pyrophosphatase (PPase), as well as changes in PPase, was investigated in rat liver in the presence of a constant physiological Mg⁺⁺ concentration during DENA (diethylnitrosamine)-induced carcinogenesis. The results were compared to liver regeneration following CCl₄ intoxication. DENA was administered over a 25 wk period; CCl₄ was given i.p. in a single dose of 0.3 ml/100 g body wt. The results in rat liver homogenates indicated that the soluble inorganic pyrophosphatase in proliferating tissues exerts a regulatory effect; enzyme activity can be influenced by Mg concentration. Enzyme alteration may be due to a dissociation of the enzyme into subunits or to a desensitization of the allosteric site in the direction of degeneration. The intracellular inorganic pyrophosphate (PP) concentration is determined by the enzyme activity and the substrate affinity. With constant Mg⁺⁺ concentration following DENA, the V_{max} of liver activity and the substrate affinity changed equally after the second week of

administration. During regeneration after CCl₄, low substrate affinity appeared to be compensated by increased total activity. Due to the allosteric properties of PPase, the Mg activation is lost when total liver activity drops after DENA or CCl₄ and, simultaneously, the mitotic activity in the tissues reaches a maximum. A difference in regeneration mechanisms between CCl₄ and DENA effects is suggested.

- 5152 AFLATOXIN B₁, A HEPATOCARCINOGEN IN THE INFANT MOUSE. (E.) Vesselinovitch, S. D. (Pritzker Sch. Med., U. Chicago, Ill.), N. Mihailovich, G. N. Wogan, L. S. Lombard and K. V. N. Rao. *Cancer Res* 32(11):2289-2291, 1972.

Aflatoxin B₁ was administered to newborn and infant C57BL X C3H F₁ mice for a further evaluation of its hepatocarcinogenicity in this species. To date, adult animals have been shown to be relatively refractory. One-, 4-, or 7-day-old groups of animals were exposed to either single or limited numbers of i.p. injections of aflatoxin B₁. Animals selected at random were sacrificed at 52 and 82 weeks of age. Newborn animals were more prone to the lethal effect of aflatoxin B₁ than the 4- or 7-day-old infants. Male infants developed hepatomas by 52 weeks of age. At 82 wk, both tumor incidence and tumor mass increased in all male groups. Seven-day-old treated females developed hepatomas, although at a low incidence rate. Thus, it was demonstrated that aflatoxin B₁ is a potent hepatocarcinogen under the experimental conditions. It was concluded that the infant age and the male hormonal environment were factors favorable for the inception and expression of liver neoplasia in mice.

- 5153 METABOLISM OF AFLATOXIN B₁ IN RHESUS MONKEYS. (E.) Dalezios, J. I. (Dept. Nutrition Food Sci., Massachusetts Inst. Technol., Cambridge) and G. N. Wogan. *Cancer Res* 32(11):2297-2303, 1972.

The metabolism of aflatoxin B₁ was investigated in male rhesus monkeys given i.p. injections of a mixture of ring-labeled aflatoxin B₁-¹⁴C and nonradioactive toxin, at a total dose of 0.4 mg/kg. Thirty-five percent of the administered radioactivity was excreted in urine within 96 hr. The excretion rate reached a maximum one hr after dosing and then fell rapidly, but urine excreted after 96 hr still contained detectable radioactivity. A new method for isolation and identification of urinary aflatoxin metabolites was devised. Of the total urinary metabolites, only 12 to 15% were chloroform extractable, including at least three fluorescent metabolites of unknown structure in addition to aflatoxins B₁ and M₁. Chloroform-insoluble metabolites were isolated on an Amberlite XAD-2 column and separated by a DEAE-Sephadex A-25 column into six subfractions. The major subfraction (60%) was hydrolyzed almost quantitatively by β -glucuronidase and the liberated metabolite was identified as aflatoxin P₁, the O-demethylation product of aflatoxin B₁. Aflatoxin P₁ in urine represented approximately 20% of the

(5154-5157)

administered dose, 17% as glucuronide, 3% as sulfate, and 1% as unconjugated phenol. Aflatoxins M_1 and B_1 in urine accounted for 2.3 and 0.01 to 0.1% of the dose, resp. Four days after injection, 5.6% of the aflatoxin dose was still retained by liver and was mainly bound to liver proteins. Radioactivity in blood attained a peak at one hr after injection, and at 96 hr it decreased to 40% of its maximum value. Gel electrophoresis of serum followed by autoradiography indicated association of the radioactivity with the albumin fraction.

skin carcinomas. The animals receiving the synthetic tar exhibited a longer survival period, the longest being 2 years, and no signs of skin carcinoma. The results confirm the possibility of using a tar which does not cause skin cancer. The fact that some inflammatory or hyperplastic skin changes were found in animals receiving the synthetic tar is explained by the continuous s.c. injections in a particular skin area. Other manifestations of skin edema or leukemias are considered to have been spontaneously evoked and not due to the tar administration, since animals receiving the solvent alone showed similar reactions. The application of this tar in certain skin diseases is proposed.

- 5154 THE EFFECT OF FRESH CIGARETTE SMOKE ON LUNG TISSUE CULTURES AND ON THE DEVELOPMENT OF LUNG TUMORS IN THE SNELL MOUSE. (Ger.) Leuchtenberger, C. (Swiss Inst. Exp. Cancer Res., Lausanne) and R. Leuchtenberger. *Schweiz Med Wochenschr* 101(38):1374-1381, 1971.

- 5156 NITROSATION OF TERTIARY AMINES AND SOME BIOLOGIC IMPLICATIONS. (E.) Iijinsky, W. (Eppley Inst. Cancer Res., Omaha, Neb.), L. Keefer, E. Conrad and R. Van de Bogart. *J Nat Cancer Inst* 49(5):1239-1249, 1972.

The relationship of cigarette smoke to carcinogenesis was studied according to two model systems: inhalation studies in animals with fresh cigarette smoke; and studies of the effects of such smoke on cell, tissue, and organ cultures. The bronchogenic carcinoma, which often occurs in human cigarette smokers, was not found in the Snell mice exposed to fresh smoke. Two other types of lung tumors were found in the animals: a benign adenoma and a malignant adenocarcinoma. Male control animals developed spontaneous tumors twice as often as did females. Following inhalation of the gas phase of cigarette smoke, the frequency of tumors increased significantly in experimental animals. This frequency increase applied to a fivefold increase of adenocarcinoma in the males and a threefold increase in the females compared with their controls. The fact that the gas phase is an important factor in carcinogenesis contradicts the notion that lung cancer develops from the particulate matter. Results of the culture experiments revealed that the alveolar macrophages in lung cultures of Snell mice have a higher degree of sensitivity toward charcoal-filtered cigarette smoke than the epithelioid cells. Exposure of lung explant cultures to the gas phase of such smoke results in a stimulation of DNA synthesis by the macrophages. The presence of macrophages appears to have a growth-regulating effect on the epithelioid cells in the lung cultures.

The reactions of a variety of trisubstituted amino compounds with nitrite were studied in mildly acid conditions (pH 3-6.5). Nitrosamines were detected in every reaction, in variable yields of up to 100%; most of these were known carcinogens. Oxidative dealkylation of trialkylamines, followed by nitrosation, occurred in near neutral buffer solution and in mildly acidic medium. Steric effects in the intermediate *N*-nitrosotrialkylammonium ion appeared to be the primary determinants of reaction course, electronic effects apparently having little influence on the results. Nucleophilic anions, such as chloride, markedly increased the yield of nitrosamine in many cases. The predictive value of the mechanistic conclusions of this work was tested and verified in studies of the nitrosation of some tertiary amines of environmental interest, including nitrilotriacetic acid, triethanolamine, and *N,N*-dimethyldodecylamine.

- 5155 COMPARATIVE STUDIES OF CARCINOGENIC ACTION OF COAL-TAR AND A NEW SYNTHETIC TAR. (Ger.) Hilfrich, J. (Med. U., Hannover, West Germany) and U. Mohr. *Arch Dermatol Forsch* 242:176-178, 1972.

- 5157 MAMMARY TUMOR REGRESSION. I. PHYSIO-PATHOLOGIC CHARACTERISTICS OF HORMONE-DEPENDENT TISSUE. (E.) Gullino, P. M. (Natl. Cancer Inst., Bethesda, Md.), F. H. Grantham, I. Losonczy and B. Berghoffer. *J Nat Cancer Inst* 49(5):1333-1348, 1972.

The carcinogenic activity of coal tar and synthetic tar was compared by injecting one group (100) of 10-week-old female MNRI mice s.c., three times weekly, with a 5% solution of Pix lithanthracis (coal tar) and a second group (100) with a 5% solution of a synthetic tar in dimethylsulfoxide. Control groups received only the solvent. None of the animals treated with coal tar survived longer than 16 months, and those who survived beyond 12 months developed

Primary 7,12-dimethylbenz[a]anthracene-induced and transplantable MTW9 mammary carcinomas of the rat were used to study the regression process of hormone-dependent tumors. Both tumors were half their initial size within a few days after the host was deprived of hormone. Chemical composition, nuclear/cytoplasmic ratios of DNA, RNA, and protein, and average DNA content/nucleus were similar in regressing and growing tumors. Vascular space, blood flow, and regulation of blood supply were similar in regressing and growing tumors. Regression could not be identified by histologic analysis until it was far advanced and tumor size was significantly reduced. Extensive invasion by immunologic-type cells was not seen in regressing tumors, except for isolated foci of macrophages

and lymphocytes, observed mostly around necrotic areas. In a group of "spontaneous" mammary tumors, no relation was found between tumor regression and functional differentiation of neoplastic cells, as measured by lactose, phosphoprotein, and triglyceride production. Transplantation of regressing MTW9 fragments into hosts with the appropriate hormonal milieu was as successful as transplantation of fragments from growing tumors. The tumor models indicated that regression consisted of a coordinated sequence of events, which occurred in the whole tumor and involved rapid destruction of single cells, but did not change significantly the relative size of the vascular, interstitial, and cellular compartments or the efficiency of the vascular system of the tumor.

- 5158 MAMMARY TUMOR REGRESSION. II. AUTOPHAGY OF NEOPLASTIC CELLS. (E.) Gullino, P. M. (Natl. Cancer Inst., Bethesda, Md.) and R. H. Lanzerotti. *J Nat Cancer Inst* 49(5):1349-1356, 1972.

MTW9-transplanted and primary, 7,12-dimethylbenz[a]-anthracene-induced mammary tumors of the rat were used to study the behavior of the pericellular environment during hormone-dependent tumor regression. Three observations are reported: 1) The sodium space/unit tumor weight did not change substantially during regression. 2) The protein and phosphorous content of the pericellular fluid remained equal in growing and regressing tumors, but the level of amino acid in efferent blood of regressing tumors was higher than that in afferent blood. This difference was not found in growing tumors. 3) The activity of six lysosomal hydrolases significantly increased in the total homogenate of regressing tumors but not in the pericellular fluid. There was no indication that the pericellular fluid of solid tumors, either growing or regressing, contained an appreciable amount of lysosomal enzymes *in vivo*. These data are interpreted to show that cell lysis, occurring during tumor regression, results from an autophagic process, i.e., an endocellular event, that is unable to alter the *in vivo* pericellular environment and does not endanger the survival of neighboring cells.

- 5159 A STUDY OF POSSIBLE CARCINOGENIC AND COCARCINOGENIC PROPERTIES OF OVERHEATED OILS. (Rus.) Dzagnidze, L. I. (Inst. Oncol. GSSR Min. Pub. Hlth, Tiflis, USSR) and P. N. Krasniyanskaya. *Soobshch Akad Nauk GSSR* 67(1):229-231, 1972.

Possible carcinogenic effects of cooking oils (butter oil and sunflower oil) heated at 160-180 C for 30-40 min were studied. A group of white mongrel rats (390) three- to five- months old, received six i.m. injections of natural or overboiled oils in a dose of 2 ml at ten-day intervals, alone or in conjunction with a single injection of 1 mg benzo(a)pyrene. Another group of animals received 1 ml of the oils eight times at ten-day intervals, alone or in conjunction with a single injection of 0.5 mg benzo(a)pyrene. Of 116 surviving rats of the first group, 19 showed

tumor development. Of 177 surviving rats of the second group, 51 had tumors. The highest tumor incidence was seen in animals which had received overheated butter oil with the single administration of the carcinogen. The control animals, which had received natural oils, did not show tumors. The latent period of tumor formation was three to four months for both groups. The tumors were rhabdomyoblastomas, polymorphous-cellular and spindle-cell sarcomas irrespective of the carcinogenic agents. Overheated oils were concluded to possess carcinogenic and cocarcinogenic properties.

- 5160 NITROSAMINE METABOLISM *IN VIVO*. I. β -OXIDATION OF ALIPHATIC DI-N-ALKYLNITROSAMINES: FORMATION OF 7-METHYLGUANINE ALONG WITH 7-PROPYL AND 7-BUTYLGUANINE RESP., FOLLOWING APPLICATION OF DI-N-PROPYL OR DI-N-BUTYLNITROSAMINE. (Ger.) Krueger, F. W. (German Center Cancer Res., Heidelberg, West Germany). *Z Krebsforsch* 76(2):145-154, 1971.

Because of the association of carcinogenesis with the alkylation of N-nitroso compounds, *in vivo* investigations of the alkylizing properties of 1- and 2-[14 C]-di-n-propylnitrosamine and of 1-[14 C]-di-n-butylnitrosamine were conducted in the ribonucleic acids of rat liver. Following doses of 388 mg/2000 microCi/kg of the first, 400 mg/2060 microCi of the second, and 371 mg/3125 microCi/kg of the third compound, the specific RNA activity was determined. The main participation of this activity is found by a labeling of pyrimidine nucleotide. The results revealed that the higher dialkylnitrosamines are metabolized to methylated compounds *in vivo*. It was demonstrated that in the 1- and 2-[14 C]-di-n-propylnitrosamines, the alkyl chain between the α - and β -C-atom must be split. The formation of 7-[14 C]-n-propyl- and 7-[14 C]-n-butyldiguanine shows, however, that besides the metabolism to methylated compounds, there is also a transference of intact alkyl groups to the genetic material.

- 5161 CERTAIN ASPECTS OF CARBOHYDRATE METABOLISM IN RAT TISSUES DURING DIMETHYLAMINOAZOBENZENE-INDUCED CARCINOGENESIS. (Rus.) Arzamastsev, V. P. (Orenburg Med. Inst., USSR). *Patol Fiziol Eksp Ter* 15(4):25-28, 1971.

Changes in glycolysis, especially in hexokinase activity, and oxygen requirement of the liver in the process of carcinogenesis were studied with 60 hybrid rats weighing 120-150 g. Dimethylaminoazobenzene (12 mg in 1 ml sunflower oil) was administered to 40 rats through a catheter in the esophagus six times a week for six months. Experimental and control animals were fed a diet low in riboflavin and protein. Biochemical and histological studies were done for two months following the end of carcinogen administration. Oxygen consumption, anaerobic and aerobic glycolysis by tissue sections of liver, kidneys, and spleen were determined, using a Warburg apparatus,

glucose as substrate and sodium pyruvate in the medium. Hexokinase activity was determined manometrically. At autopsy, dystrophic and cirrhotic changes were seen in the liver of experimental animals, indicating precancerous changes. Biochemical studies showed intensification of anaerobic and aerobic glycolysis due to the high concentration of oxidized nicotinamide-adenine-dinucleotide in experimental livers. There was an increase in hexokinase activity in the liver homogenates of experimental animals (160%). Hexokinase activity was also increased in the kidneys and spleen of experimental animals (142% in the kidneys and 137% in the spleen). Intensification of glycolysis in these organs could not be determined. Oxygen consumption by the control and experimental liver tissues was the same (2.3 mm³/hr). Oxygen consumption was the same in experimental and control kidneys (9 mm³/hr). Oxygen consumption in the control spleen was higher (4.8 mm³/hr) than in the experimental spleen (3.9 mm³/hr).

5162 INDUCTION OF CARDIAC TUMORS IN BD RATS BY CONTINUOUS ORAL ADMINISTRATION OF THE CARCINOGEN 1-PYRIDYL-3,3-DIETHYL-TRIAZENE (PDAT). (Ger.) Ivankovic, S. (German Cancer Res. Ctr., Heidelberg, West Germany), H. Wohlenberg, H. D. Mennel and R. Preussmann. *Z Krebsforsch* 77(3):217-225, 1972.

BD rats, aged 3 months, received 2 or 4 mg/kg of the carcinogen 1-pyridyl-3,3-diethyl-triazene (PDAT) in their drinking water (five days per week). The development of cardiac tumors was confirmed clinically by the manifestation of dyspnea and subacute edema. The first malignant tumors were observed one yr after the beginning of the administration of the carcinogen. Of 25 rats given 2 mg/kg doses, ten animals died within 414-712 days. These had malignant cardiac tumors. Of 19 animals given 4 mg/kg, five times weekly, six animals died without developing tumors, and six others showed the beginnings of cardiac tumors at autopsy. These tumors were only discovered upon dissection of the heart. The mean induction time was 500 days. It appears that cardiac tumors occurred more frequently in the animals receiving the lower doses of carcinogen, although tumors in other organs were found less frequently in this group than in the group receiving double the dose. It thus follows that the heart is more sensitive to PDAT than are other organs.

5163 ULTRASTRUCTURAL CHANGES IN RAT LIVERS INDUCED BY REPEATED INJECTIONS OF TRYPAN BLUE. (E.) Gillman, T. (Inst. Animal Path., Cambridge, England) and R. C. Hallows. *Cancer Res* 32(11):2393-2399, 1972.

Repeated injections of trypan blue into the s.c. tissue of inbred Wistar rats induced tumors in the liver. The morphological changes that occurred during induction of the tumors were studied ultrastructurally. The earliest recognized change was the appearance in the portal tracts of focal collections

of monocytic cells that resembled Kupffer cells. They appeared either to collect in the periportal connective tissue or to migrate through the endothelial wall and collect within the portal venules or lymphatics. This caused periportal cyst formation and pressure atrophy of the surrounding hepatocytes. No mitotic activity was seen in the monocytic cells, but their numbers increased and occluded lymph flow. The more numerous these cells became, the less they resembled Kupffer cells and the more they came to resemble cells of the established tumors. Collagen fibrils and bundles as well as fibrin appeared among the cells. Subsequently, nonperiodic fibrillar material was also seen around the cells. The cellular areas were then indistinguishable from established primary tumors. The morphological changes seen in the liver resemble those reported in histopathological descriptions of Kupffer cell sarcoma in humans.

5164 GENETIC PROPERTIES OF SUBSTITUTED DERIVATIVES OF *N*-METHYL-4-AMINOAZOBENZENE IN RELATION TO AZO-DYE CARCINOGENESIS. (E.) Fahmy, O. G. (Inst. Cancer Res., London, England) and M. J. Fahmy. *Int J Cancer* 10:194-206, 1972.

N,N-dimethyl-4-aminoazobenzene (DAB) and several of its analogous substituted derivatives were injected into the hemocoel of *Drosophila melanogaster*; mutagenicity of the compounds for the heterochromatic *bobbed* (*bb*) and *Minute* (*M*) loci relative to general mutability as indicated by the overall response of the X-chromosome (recessive lethals and visibles), was observed. DAB and its 3'-Me and 3'-ClMe derivatives did not raise X-mutation frequencies above control levels, nor did these compounds increase mutation frequencies at selected euchromatic loci investigated with the *bb* loci. The *N*-benzoyloxy derivative of DAB (*N*-BzO-MAB) raised X-chromosome mutation frequencies, as did chloroethylamines (*N*-ClEt-MAB). DAB and its 3'-Me analog, and *N*-substituted reactive DAB derivatives were all mutagenic for the heterochromatic *nucleolar organizer* region of the X-chromosome, a major r-RNA-forming segment. *N*-BzO-MAB was a more active mutagen than DAB for these regions. DAB increased maximal X-mutation frequencies in spermatogonia, as did its 3'-Me derivative. Mutagenicity of both DAB and of *N*-BzO-MAB were maximal in spermatogonia. The mutagenicity and/or gene selectivity on the *bb* loci activity of tested azo dyes was correlated with the carcinogenicity of the tested agents, the most selective and mutagenic dyes (DAB, its 3'-Me derivative and *N*-BzO-MAB) being strong hepatocarcinogens.

5165 STUDIES ON CARCINOGENIC TRYPTOPHAN METABOLITES. II. ENZYMATIC FORMATION AND HYDROLYSIS OF SULFURIC ESTER OF 3-HYDROXYANTHRANILIC ACID. (E.) Watanabe, M. (Natl. Inst. Hyg. Sci., Tokyo, Japan) and K. Minegishi. *Biochem Pharmacol* 21(9):1347-1356, 1972.

The enzyme that forms the sulfuric ester of 3-hydroxyanthranilic acid (3-OHAA) was precipitated from livers of guinea pigs, rats and DDN mice by

(NH₄)₂SO₄. Enzymes were preincubated with ATP and SO₄²⁻, then incubated with 3-OHAA for 60 min. The rate of formation of the sulfuric ester of 3-OHAA (3-OSAA) was determined fluorometrically; at the same time, the formation of p-nitrophenylsulfate (NPS) was estimated. 3-OSAA was formed by enzymes from all three species. The ratio of formation of 3-OSAA and (NPS) per mg protein was 0.23:1, 0.45:1 and 0.39:1 in guinea pigs, mice and rats, resp. The rate of hydrolysis of 3-OSAA by the enzyme from human urine was 0.065 times the rate of hydrolysis of 2-hydroxy-5-nitrophenylsulfate. These results suggest that formation of 3-OSAA is possible in the animal body that hydrolysis of 3-OSAA may be negligible in urine.

- 5166 DIFFERENCES IN (Mg²⁺) AND (Ca²⁺) DEPENDENCE OF AMINO ACID INCORPORATION BY FREE AND MEMBRANE-BOUND POLYRIBOSOMES ISOLATED FROM LIVER AND AN EFFECT OF THE HEPATOCARCINOGEN DIMETHYLNITROSAMINE. (E.) Vernie, L. N. (Netherlands Cancer Inst., Amsterdam), W. S. Bont and P. Emmelot. *Biochim Biophys Acta* 281(2):253-262, 1972.

Free and membrane-bound polyribosomes were isolated from livers of normal rats and rats given a single i.v. injection of 50 mg dimethylnitrosamine (DMNA) per kg five hr previously. Amino acid incorporation by polyribosomes was studied in the presence of 2-8 mM Mg²⁺ and 0-5 mM Ca²⁺. Ca²⁺ in combination with Mg²⁺ was more effective than Mg²⁺ alone in sustaining amino acid incorporation by free polyribosomes. Optimal incorporation occurred at 6 mM Mg²⁺ and 2-3 mM Ca²⁺. The breakdown of free polyribosomes during amino acid incorporation at Mg²⁺ levels below 7 mM was counteracted by Ca²⁺. Amino acid incorporation depended on the relative concentrations of the two ions rather than on their sum concentration. Ionic conditions for incorporation were not changed by DMNA action. The Mg²⁺ dependence of amino acid incorporation by membrane-bound polyribosomes differed from that of free ribosomes, optimal incorporation occurring at 4 mM Mg²⁺ and 2 mM Ca²⁺. Also, various Ca²⁺ concentrations stimulatory or not active for amino acid incorporation by free polyribosomes were inhibitory in the case of the membrane-bound ribosomes. The relative effects of various Ca²⁺ concentrations on DMNA preparations at 6 and 4 mM mg²⁺ were similar to those on normal preparations at, resp., 8 and 6 mM Mg²⁺. Thus, DMNA affected the ionic conditions for amino acid incorporation by membrane-bound polyribosomes by causing a shift to a lower requirement for added ions.

- 5167 BIOCHEMICALLY DIFFERENTIATED NEOPLASTIC CLONE OF SCHWANN CELLS. (E.) Pfeiffer, S. E. (Dept. Microbiol., U. Connecticut, Storrs) and W. Wechsler. *Proc Nat Acad Sci USA* 69(10):2885-2889, 1972.

Malignant neurinomas were induced in rats by a single i.v. injection of 80 mg ethylnitrosourea. Four clones were established from one of these

tumors, a transplantable tumor of the cervical spinal-nerve root. One clone (RN-2) possessed some properties of Schwann cells. It contained the nervous system specific protein S-100 as 0.1% of total soluble protein; showed high levels of 2',3'-cyclic nucleotide-3'-phosphohydrolase, an enzyme found in large amounts only in glial cells; and produced a basic protein related by immunological cross-reaction, molecular size, and amino-acid composition to the encephalitogenic protein from beef brain myelin. RN-2 grew in monolayers with a doubling time of 20 hr and a plating efficiency of 50%. Its cells had a mode of 43 normal chromosomes. Inoculated s.c. in rats, cells of this clone grew as tumors.

- 5168 DETERMINING ROLE OF AGE AND THYMUS IN PATHOLOGY OF 7,12-DIMETHYLBENZ(A)ANTHRACENE-INDUCED LEUKEMIA IN MICE. (E.) Shisa, H. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan) and Y. Nishizuka. *Gann* 62(5):407-412, 1971.

Leukemia incidence was investigated in five groups of Swiss/Ms mice injected in the intrascapular s.c. area with a lipid emulsion of 7,12-dimethylbenz(a)-anthracene (DMBA). Group 1 consisted of three-day old mice; group 2 of 35-day old mice; group 3 of 35-day-old mice pretreated with cortisone; group 4 of 70-day-old mice; and group 5 of female mice injected three days after parturition (average age, 71 days). Group 1 received 100 µg DMBA and the other groups 1 mg. Leukemias developed in all groups. Thymic lymphocytic or lymphoblastic leukemias developed in 96.5, 50.0 and 26.1% of animals in groups 1, 2 and 4, resp. In groups 3 and 5, the percentages of thymic leukemias were 91.3 and 71.4%, resp. Non-thymic leukemias were classed as undifferentiated cell leukemias. These were more common in adult mice. Thymuses in cortisone-treated mice and in postpartum mice showed prompt weight decreases followed by increases as lymphocytes diminished, then proliferated.

- 5169 FINE STRUCTURAL CHANGES IN RAT PANCREATIC CELLS DURING PROLONGED TREATMENT WITH 4-ACETYLAMINOFLUORENE. (E.) Flaks, B. (U. Bristol Med. Sch., England) and J. Lucas. *Chem-Biol Interact* 5(4):217-225, 1972.

Male rats were fed the noncarcinogen 4-acetylaminofluorene (4-AAF) as 0.05% of diet. The rats were killed after 7-10 days, 3-4 wk, 8-12 wk, or 8-10 months on the diet and pancreatic acinar cells were prepared for electron microscopic examination. After 7-10 days on 4-AAF, some acinar cells showed lesions of the granular endoplasmic reticulum. The cisternae of granular endoplasmic reticulum were much dilated, as was the perinuclear envelope. By 8-12 wk, most acinar cells exhibited changed granular endoplasmic reticulum, and large autophagic vacuoles had begun to appear in many acinar cells. Some mitochondrial damage and focal cytoplasmic degradation was also seen in acinar cells. By 8-10 months, mitochondrial damage was still evident, but dilation of the granular endoplasmic reti-

culum was less severe. The changes produced in pancreatic acinar cells by 4-AAF were similar to changes produced by the carcinogenic 2-AAF. However, 4-AAF did not appear to inhibit secretory enzyme protein transport; this inhibition was one of the effects of 2-AAF on pancreatic acinar cells.

- 5170 THYROID CARCINOGENESIS IN HAMSTERS AFTER TREATMENT WITH ^{131}I -IODINE AND METHYLTHIOURACIL. (E.) Christov, K. (Cancer Res. Inst., Sofia, Bulgaria) and R. Raichev. *Z Krebsforsch* 77(3):171-179, 1972.

Female hamsters were given methylthiouracil (MTU) as 0.2% of drinking water and/or ^{131}I (i.p. injections of 10 μCi). The hamsters were killed at various intervals and their thyroids were examined. Thyroid adenomas were first found in MTU-treated animals five months after the start of MTU-feeding; by the end of a yr, 58% of MTU-treated hamsters had thyroid adenomas of a papilliferous type. Small papilliferous adenomas were also seen in hamsters given ^{131}I , beginning eight to 12 months after the start of treatment. Thyroid adenomas appeared as early as the fourth month in hamsters given MTU and ^{131}I . In the combined-treatment group, the thyroid adenomas were more numerous and larger than in hamsters given MTU or ^{131}I only. In the fifth month thyroid carcinomas were seen in this group.

- 5171 EARLY CHANGES IN RAT ADRENAL PROTEIN SYNTHESIS AFTER DIMETHYLNITROSAMINE ADMINISTRATION. (E.) Bauer, G. E. (Dept. Anat., U. Minnesota, Minneapolis), E. A. Smuckler and T. Hultin. *Proc Soc Exp Biol Med* 140(4):1402-1404, 1972.

Male rats were given dimethylnitrosamine (DMNA) by gastric intubation (20 mg/kg) or by i.p. injection (20 mg/kg). Some rats given DMNA i.p. were also given Celite (acid-washed diatomaceous earth) (225 mg/kg) in i.p. injections. The incorporation of ^{14}C -leucine into protein in adrenals of rats given DMNA was observed as an index of adrenal protein synthesis. Intragastric DMNA caused a prompt increase of more than 50% in ^{14}C -leucine uptake, with a return to control levels by eight hr. Treatment of adrenal slices *in vitro* with DMNA produced a 16% decrease in amino acid uptake; liver slices treated with DMNA *in vitro* showed a marked inhibition of ^{14}C -leucine uptake. Intraperitoneal injection of DMNA caused a prompt increase in ^{14}C -leucine uptake by adrenals. Amino acid uptake reached its maximum by two hr, fell to near control levels by four hr, and rose again at 12 hr, finally to return to normal by 24 hr. In rats given Celite along with i.p. DMNA, ^{14}C -leucine uptake showed a more prolonged and sustained stimulation.

- 5172 ETHYLATION OF NUCLEIC ACIDS BY ETHYLNITROSOUREA- ^{14}C IN THE FETAL AND ADULT RAT. (E.) Goth, R. (Max-Planck Inst., Tübingen, West Germany)

and M. F. Rajewsky. *Cancer Res* 32:1501-1505, 1972.

Pregnant female rats were injected i.v. with 75 $\mu\text{g/g}$ body wt *N*-ethyl-*N*-nitroso-urea- ^{14}C (ENU), an amount representing 30% of the 50% lethal dose for these rats. One hr later, fetuses, brains and livers were removed and the formation of the ENU alkylation product 7-ethylguanine (7-EG) in nucleic acids of fetal and adult brain and liver was examined by ion-exchange radiochromatography. The degree of ethylation of ENU (expressed as the fractions of guanine residues ethylated (7-EG:guanine)) in whole fetus nucleic acids was 1.7×10^{-5} for DNA and 0.6×10^{-5} for RNA. The 7-EG:guanine value for fetal brain DNA was 2.2×10^{-5} and the 7-EG:guanine value for fetal liver DNA was 4.4×10^{-5} . The corresponding values for adult brain and liver were 2.1×10^{-5} and 3.5×10^{-5} , resp. These findings indicate that the tumorigenic effect of an alkylating carcinogen is not a simple function of the degree of *N*-7-alkylation produced in the nucleic acids.

- 5173 INFLUENCE OF "FEEDER CELLS" AND INDUCERS AND INHIBITORS OF MICROSOMAL MIXED-FUNCTION OXIDASES ON HYDROCARBON-INDUCED MALIGNANT TRANSFORMATION OF CELLS DERIVED FROM C3H MOUSE PROSTATE. (E.) Marquardt, H. (McArdle Lab. Cancer Res., U. Wisconsin, Madison) and C. Heidelberger. *Cancer Res* 32(4):721-725, 1972.

Irradiated (5,000 R) rat or mouse embryo fibroblasts ("feeder cells") were added to G23 C3H mouse prostate fibroblasts; the feeder cells were known to metabolize polycyclic aromatic hydrocarbons, while G23 cells metabolized hydrocarbons poorly. Various carcinogens were added to the feeder cell-G23 mixtures and hydrocarbon-induced cytotoxicity, plating efficiency of cells and hydrocarbon-induced malignant transformation was observed. Feeder cells greatly increased hydrocarbon metabolism in G23 cells, and also increased plating efficiency of prostate cells and cytotoxicity of 3-methylcholanthrene (MCA) and 7,12-dimethylbenz(a)anthracene (DMBA). Feeder cells did not affect the cytotoxicity of the K-region epoxide of MCA. Malignant transformation of G23 cells by MCA was increased by feeder cells; but transformation by DMBA was not affected and transformation by MCA's K-region epoxide was reduced. Irradiated human skin cells used as feeders had no effect on plating efficiency, hydrocarbon-induced cytotoxicity, or hydrocarbon-induced transformation. Induction of microsomal mixed-function oxidases in G23 cells by benz(a)anthracene (BA) or 2,5-diphenyl-oxazole increased cytotoxicity of MCA, BA and DMBA but did not affect cytotoxicity of MCA's K-region epoxide. Malignant transformation in G23 cells by BA and MCA was increased by enzyme induction, but DMBA transformation was not affected. Transformation by MCA's K-region epoxide was reduced by enzyme induction in G23 cells. Inhibition of microsomal mixed-function oxidases by α -naphthoflavone decreased the cytotoxicity of MCA and increased that of its K-region epoxide. Enzyme inhibition prevented MCA transformation, but enhanced transformation by its K-region epoxide.

- 5174 STRUCTURE-ACTIVITY RELATIONSHIPS IN DNA BINDING AND NUCLEAR EFFECTS OF AFLATOXIN AND ANALOGS. (E.) Edwards, G. S. (Dept. Nutr. Food Sci., Massachusetts Inst. Technol., Cambridge), G. N. Wogan, M. B. Sporn and R. S. Pong. *Cancer Res* 31:1943-1950, 1971.

Aflatoxins B₁, B₂ and G₁ and three synthetic compounds were evaluated for their ability to inhibit RNA polymerase activity, decrease the nuclear content of RNA and cause nucleolar macrosegregation in rat hepatocyte nuclei. The ability of each of the compounds to bind to native calf thymus DNA was studied by equilibrium dialysis. 5,7-Dimethoxycyclopentenone [2,3-c]coumarin (compound 11) had the highest association constant followed, in decreasing order, by aflatoxins B₁, B₂ and tetrahydrodeoxyaflatoxin B₁. The DNA-binding capacity of these compounds did not reflect their toxic or carcinogenic activity. The ability of aflatoxins B₁, B₂ and G₁ to inhibit Mg⁺⁺- and Mn⁺⁺-stimulated RNA polymerase correlated with carcinogenic activity. Assay of liver homogenates from pretreated rats showed that aflatoxins B₁ and G₁ inhibited both polymerase activities by about 40% and 35%, resp., while aflatoxin B₂ had no effect. Aflatoxin B₁ was more active in causing RNA degradation (reduction in RNA:DNA ratio) in hepatoma nuclei isolated from treated rats than was aflatoxin G₁; aflatoxin B₂ showed no effect at a dose 100 times that of aflatoxin B₁. Aflatoxins B₁ and G₁ produced a rapid macrosegregation of the fibrillar and granular portions of the hepatocyte nucleolus. Aflatoxin B₂ induced only minimal segregation (microsegregation). Coumarin, tetrahydrodeoxyaflatoxin B₁, aflatoxin G₂ and three carcinogenically inactive aflatoxin analogs caused no observable ultrastructural changes. Rats were given i.p. injections of ring-labeled aflatoxins B₁-¹⁴C or B₂-¹⁴C, sacrificed after three hr and examined to determine the extent of metabolism of the two compounds. The noncarcinogenic aflatoxin B₂ was catabolized and excreted from the liver twice as fast as the carcinogenic aflatoxin B₁. However, this difference was not sufficient to account for the large differences in acute activities of these two compounds.

- 5175 *IN VITRO* INCREASE OF THE LIFE SPAN OF HAMSTER EMBRYO CELL CULTURES TREATED WITH CHEMICAL CARCINOGENS. (Rus.) Irlin, I. S. (N. F. Gamaleya Inst. Epidemiol. Microbiol., Acad. Med. Sci. USSR, Moscow) and I. I. Parkhomenko. *Vop Onkol* 17(11):62-68, 1971.

The effects of various chemical carcinogens on trypsinized cultures of late pregnancy hamster embryos were studied. The carcinogens used were 3,4-benzo(a)pyrene (BP), 7,12-dimethyl-1,2-benzanthracene (DMBA), 20-methylcholanthrene (MCA), pyrene (P), and anthracene (A). The nutritive medium contained 10% inactivated bovine serum medium. To study the sensitivity of the transformed cells to toxic effects of the carcinogens, the cells were inoculated into a Petri dish filled with a growth medium containing various doses of the above carcinogens. For the study of transplantability of the

cultures *in vivo*, various doses of cells in a growth medium were injected s.c. into hamsters. From 21 primary cultures grown in the presence of MCA in doses 2, 6, 10, and 20 µg/ml, 18 cell lines (86%) were obtained after 3-4 months. They survived 55-60 passages for 1.5 yr. All 26 control cultures of embryonic hamster tissue degenerated after 5-6 passages. Only one of eight cultures treated with DMBA (0.5-1 µg/ml) for 48 hr produced a new cell line. Two cell lines (from the culture treated with 5 µg/ml) were obtained from nine cultures treated with BP (1, 2, 5 and 10 µg/ml) for 3-6 days. Incubation with Tween 80 (400-450 µg/ml) for 28 hr to eight days before or after treatment with BP or MCA shortened the time for transformation of cultures into cell lines to 2-3 months. Inoculation of stable cultures (85-160 days of growth *in vitro*) treated with MCA into adult hamsters induced tumors (25/58 hamsters).

- 5176 RESPIRATORY TRACT CARCINOGENESIS INDUCED IN HAMSTERS BY DIFFERENT DOSE LEVELS OF BENZO[a]PYRENE AND FERRIC OXIDE. (E.) Saffiotti, U. (Nat. Cancer Inst., Bethesda, Md.), R. Montezano, A. R. Sellakumar and D. G. Kaufman. *J Nat Cancer Inst* 49(4):1199-1204, 1972.

Dose-response relationships in respiratory tract tumor induction were investigated in Syrian golden hamsters given 30 weekly intratracheal instillations of 0.25, 0.5, 1.0, or 2.0 mg benzo(a)pyrene mixed with equal amounts of Fe₂O₃. A positive correlation was demonstrated between the dose level of individual administrations and the yield of respiratory tumors. Both tumor latency and tumor multiplicity were related to the dose per administration and hence total dose. As previously noted in this animal model, squamous cell carcinomas were the predominant morphologic type, and the most frequently affected site was the bronchi, followed by the trachea.

- 5177 CONVERSION OF CARCINOGENIC HYDROCARBONS IN TUMOR CELL CULTURES. (Rus.) Bakulina, S. P. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow), C. A. Belitskii, I. M. Buzhurina and M. A. Panov. *Vopr Onkol* 18(7):65-68, 1972.

Formation of metabolites of benzpyrene and 7,12-dimethylbenzanthracene was studied spectrometrically in normal fibroblastoid hamster cells and in cell lines of fibroblasts transformed by polyoma and SV40 viruses--610, 70/0, and CA-1 (used in a previous work). H³-benzpyrene and acid-soluble metabolites did not accumulate in cultures of CA-1 line cells during 1-72 hr of incubation. H³-benzpyrene accumulated somewhat in firmly combined form in cultures of 70/0 and 610 line cells, but acid-soluble H³-benzpyrene metabolites did not accumulate in these cell cultures. Acid-soluble metabolites of H³-dimethylbenzanthracene did not accumulate in the normal fibroblastoid cells during 24-72 hr of incubation, while H³-dimethylbenzanthracene derivatives which combine with cells and pro-

tein increased somewhat in these cells. H^3 -dimethylbenzanthracene derivatives were not seen in the transformed cells (70/0, 610, and CA-1 cells). Benzpyrene metabolism was accompanied by an accumulation of the acid-soluble metabolites in normal cell cultures, but these metabolites were not seen in the transformed cell cultures. Dimethylbenzanthracene was metabolized significantly more slowly than benzpyrene in normal cell cultures.

5178 TUMORS OF THE NERVOUS SYSTEM FOLLOWING INTRAPERITONEAL INJECTION OF METHYLNITROSOUREA. (Ger.) Schreiber, D. (Med. Acad. Erfurt, East Germany), P. Scholtze, W. Jänisch and H. Batka. *Zentralbl Allg Pathol* 115(1/2):3-7, 1972.

Methylnitrosourea (MNU) was administered i.p. to rats for the induction of tumors of the nervous system, and the results compared with those obtained with i.v. injections in a previous study. The tests were conducted in newborn, young and adult Hauben rats (groups I-VI) and in adult Wistar rats (group VII). With the exception of groups V and VI, which were all males, the animals were of both sexes. Groups I, III, and VII received 10 mg/kg MNU in buffer solution at pH 4.2-4.4, biweekly, i.p. and the other four groups received twice this dose every four weeks. The rats in groups V and VI were castrated before the beginning of the experiments or given i.m. injections of testosterone, resp. Tumors of the nervous system were demonstrated in 40.7% of the Wistar rats and in 75.9% of the Hauben rats; this incidence was comparable to the results of i.v. administration of MNU. Multiple tumors were observed in 36.1% of the Hauben rats and in 3.7% of the Wistar rats. The induction time of tumors was much shorter in the younger animals, although frequency of tumors was not affected by age; no significant differences were found due to dose levels, castration or treatment with testosterone. The tumors included gliomas, sarcomas, gliosarcomas, neurinomas, neurosarcomas and one meningioma. The simpler i.p. technique was as effective as the i.v., for tumor induction in rats.

5179 CULTURE OF MAMMALIAN BUCCAL CELLS. II. A STUDY OF THE ACTION OF ATMOSPHERIC MICROCONSTITUENTS. (Fr.) Frappa, J. (Microbiol. Div., C.R.S.S.A., Lyon, France), P. Deschaux, C. Bottex and R. Fontanges. *C R Seances Soc Biol* 165(7/8):1633-1638, 1971.

Oxygen consumption and glucose incorporation were studied in embryonic calf buccal cell cultures and tissue explants inoculated with up to 1000 μ g atmospheric organominerals, up to 400 μ g natural carcinogenic hydrocarbons, and up to 100 μ g synthetic carcinogenic hydrocarbons. The cell cultures and tissue explants were examined 1 and 48 hr after contact with the pollutants. Oxygen consumption in cell cultures was depressed by organomineral complexes in the first hr but was increased after 48 hr. The increase

was proportional to the concentration of pollutants. Low concentrations of the organic fraction tended to decrease O_2 consumption, while higher concentrations increased it. In tissue explants, O_2 consumption was low with a mixture of microconstituents, markedly decreased by the organic fraction, and increased by the mineral fraction. The results were similar for glucose consumption. The particular effect of the organic fraction was confirmed by the study of the effects of benzo(a)pyrene, benzanthracene, benzperylene, and coronin. Their effect on cell cultures was comparable to that of the organic fraction.

5180 TEST OF ALCOHOLIC BEVERAGES AND ETHANOL SOLUTIONS FOR CARCINOGENICITY AND TUMOR-PROMOTING ACTIVITY. (E.) Kuratsune, M. (Fac. Med., Kyushu U., Japan), S. Kohchi, A. Horie and M. Nishizumi. *Gann* 62(5):395-405, 1971.

Wistar rats and CF_1 and ddN mice were subjected to chronic treatment with Japanese or Scotch whiskey, sherry, *Sake*, and an aqueous solution of ethanol. The agents were administered by forced drinking, skin painting or s.c. injection. No malignant tumors which could be ascribed to chronic treatments were seen. In tumor promotion experiments, topical applications of 7,12-dimethylbenz(a)anthracene were followed by topical applications of distillation residues of *Sake* and whiskey. *Sake* and whiskey distillates, used as tumor promoters, increased tumor development over that in animals given carcinogens with no promoter; however, the differences in tumor incidence were not statistically significant.

5181 THE ROLE OF DNA CROSS-LINKING IN THE INACTIVATION OF BACTERIOPHAGE T_7 BY CARCINOGENIC BROMOMETHYLBENZ(a)ANTHRACENES. (E.) Venitt, S. (Roy. Cancer Hosp., London, England) and K. V. Shooter. *Biochim Biophys Acta* 277(3):479-488, 1972.

T_7 bacteriophage DNA was exposed to the carcinogens 7-bromomethylbenz(a)anthracene or 7-bromomethyl-12-methylbenz(a)anthracene, then denatured to determine the extent of DNA cross-linking induced by the compounds. Both compounds induced heat-stable and alkali-stable interstrand cross-links in T_7 DNA. There was a dose-dependent increase of carcinogen binding to DNA and a concomitant increase in DNA cross-linking. It was calculated that 1700 7-bromomethyl-12-methylbenz(a)anthracene residues and 4890 7-bromomethylbenz(a)anthracene residues, resp., were needed to produce one cross-link in a T_7 DNA molecule of molecular wt 2.5×10^7 . The effects of the two carcinogens on the survival of T_7 plaque formation was investigated in related experiments. No significant inactivation of T_7 by 7-bromomethyl-12-methylbenz(a)anthracene was seen, though 7-bromomethylbenz(a)anthracene caused inactivation of T_7 plaque formation. This inactivation followed single-hit kinetics; the extents of reaction reducing T_7 survival of plaque formation

to 37% were 6.2 arylalkylations/T7 DNA molecule and 2.5 arylalkylations/total coat protein, resp.

- 5182 DEGRADATION OF STEROIDS BY INTESTINAL BACTERIA. IV. THE AROMATIZATION OF RING A. (E.) Goddard, P. (St. Mary's Hosp. Med. Sch., London, England) and M. J. Hill. *Biochim Biophys Acta* 280(2):336-342, 1972.

E. coli or *C. paraputrificum* were incubated anaerobically with the substrate 4-androsten-3,17-dione. After anaerobic growth for 72 hr some cultures were exposed to disruption by ultrasound (assay system 2), while others were simply exposed to aerobic conditions (assay system 1). Substrate and metabolite were examined by thin-layer chromatography. In assay 1, *E. coli* produced estradiol as a metabolite from 4-androsten-3,17-dione. *C. paraputrificum*, in the same assay system, produced two metabolites, one of which was relatively nonpolar compared to estradiol or estrone. This metabolite was identified as 17-methoxy-1,3,5(10)-estratriene-3-ol following analysis of its UV and fluorescence spectra, its mass spectrum and its trifluoroacetyl derivative. In assay system 2, no aromatization of substrate occurred unless bacteria had been grown in the presence of the substrate. This suggested that inducible enzymes were involved in the aromatization.

- 5183 HISTOPATHOLOGICAL ANALYSIS OF KIDNEY TUMORS IN RATS INDUCED BY CHEMICAL CARCINOGENS. (E.) Ito, N. (Nara Med. U., Japan), Y. Hiasa, Y. Kamamoto, S. Makiura, S. Sugihara, M. Marugami and E. Okajima. *Gann* 62(6):435-444, 1971.

Wistar, Sprague-Dawley and BDIX rats were treated with carcinogens as follows: basic lead acetate as 1.5% of diet; N-nitrosodimethylamine injected s.c. (0.1 mg/rat) or in diet (500 ppm); N-butyl-N-(4-hydroxybutyl)nitrosamine as 0.05% solution in drinking water; 3-methylcholanthrene (0.2 mg) by a cotton kidney implant impregnated with the agent; 4-nitroquinoline 1-oxide (0.4 mg) administered in the same manner as 3-methylcholanthrene. Kidney tumor incidence was observed. All rats given basic lead acetate developed renal cell tumors (adenomas, clear cell carcinomas and dark cell carcinomas); no other types of kidney tumors were induced by basic lead acetate. Of rats given N-nitrosodimethylamine, 14.4% had renal cell tumors, 83.2% had embryonal cell tumors and 2.4% had hemangioendotheliomas. Of rats given N-butyl-N-(4-hydroxybutyl)nitrosamine, 4.2% had embryonal cell tumors and 95.8% had transitional cell tumors. All rats given either 3-methylcholanthrene or 4-nitroquinoline 1-oxide had transitional cell tumors; none had tumors of the other three types.

- 5197 EXPERIMENTAL BRONCHOPULMONARY CANCER IN THE RAT BY INHALATION OF RADON. COMPARISON WITH MORPHOLOGICAL ASPECTS OF HUMAN CANCERS. (Fr.) Perraud, R. (Atom. Energy Commis., Paris, France), J. Chameaud, J. Lafuma, R. Masse and J. Chretien. *J Fr Med Chir Thorac* 26(1):25-41, 1972.

The effects of radon inhalation were studied in rats to test the hypothesis that such inhalation will not induce pulmonary tumors where no preexisting lesion is present. Two pieces of equipment were used: one for inhalation of radon and another for inhalation of ceric hydroxide, a substance known to cause tissue reactions. In one experiment, the animals were first exposed to ceric hydroxide, amounting to 0.5-1 mg in the lungs of each rat. These animals were then exposed to radon three days a week for five hr, for a period of 10 months. In a second experiment the rats were exposed to radon only, for five hr daily for a total exposure of 620 hr, the mean radon concentration being 7.5×10^{-7} curie/liter as in the first group. All animals who survived to the 11th month following the beginning of the experiment exhibited pulmonary cancers, regardless of preexisting lesions. These tumors were multiple and predominantly distal. From the morphological viewpoint, it appears that carcinogenesis may be induced in rats (which are resistant to spontaneous pulmonary malignant tumors) with all the features described in human bronchopulmonary carcinomas, except for anaplastic carcinomas with small cells. The apparatus is recommended for further studies in inhalation.

- 5198 DOSE TO OSTEOGENIC CELLS FROM PLUTONIUM-239 DEPOSITED IN RAT BONE. (E.) James, A. C. (Roy. Free Hosp. Sch. Med., London, England). *Radiat Res* 51(3):654-673, 1972.

Male Marshall-August rats, seven wk old, were injected i.v. with 4.5 μ Ci/kg body wt soluble $\text{Pu}(\text{NO}_3)_4$. Between one and 48 hr later, the rats were killed and their femora and vertebra examined for ^{239}Pu content. Soon after injection, average ^{239}Pu dose rates to bone tissue, at distances of 5, 12.5 and 20 μ m into the narrow space, ranged from 58, 38 and 26 rads/day to 22, 12 and 7 rads/day on different endosteal surfaces. These local dose rates changed with time by factors on the order of 2, in either direction. There were significant differences, between bones, in plutonium distribution and dose to osteogenic cells. Cumulative doses above 2000 rads delivered at 20 μ m from trabecular surfaces were associated with a 5-10% probability of producing an osteosarcoma.

- 5199 THE SEMINAL GLAND TUMORS INDUCED BY CELLOPHANE. (Rus.) Korobko, Yu. A. (A. N. Severtsov Inst. Animal Ecol. Morphol., Moscow, USSR). *Vopr Onkol* 18(8):65-69, 1972.

In 40 male white rats (85-110 g), the left testicle was wrapped with sterile cellophane film two or three times. This resulted in the formation of 19

tumors, the first of which appeared after 13 months. Altogether, 24 rats survived 13 months. Metastases in intestinal and spinal muscles were observed in four cases. The tumors obtained were hard to classify but were not teratomas. However, the tumors were spindle-shaped and polymorphous fibroblastoid cells. Two chondral tumors and two seminomas were also observed. All the tumors were considered to be induced by cellophane because of their localization in the testicle, the absence of cellophane inside the tumors and its presence in the periphery of the tumors.

- 5200 RADIATION-INDUCED HAIR-FOLLICLE DAMAGE AND TUMOR FORMATION IN MOUSE AND RAT SKIN. (E.) Albert, R. E. (New York U. Med., Ctr., N.Y.), F. J. Burns and P. Bennett. *J Nat Cancer Inst* 49(4):1131-1137, 1972.

The dorsal skin of 158 Swiss Millerton mice was irradiated with electrons in single exposures at six dose levels from 500-4000 rads. The mice were observed for skin-tumor formation every four wk for 88 wk. At death each tumor was examined histologically, and whole-skin mounts were used to determine the survival of intact hair follicles and the incidence of atrophic follicles. These data were compared with the dose-response characteristics for tumor induction and hair-follicle survival in the rat from previous experiments. The incidence of epithelial skin tumors was markedly lower in mice than in rats, the greatest number of epithelial tumors for any dose group was three in an average group of 21 mice compared with rat maximal response of 4.0 tumors/rat. This difference was due to the failure of mice to develop adnexal tumors, which are the predominant type of skin tumor in the rat. In the mouse the highest atrophic follicle incidence was only about 6%, when the total follicle survival was only about 15-20%. In the rat the highest atrophic follicle incidence was about 20%, when the total follicle survival time was about 50-60%. The relatively low level of atrophic follicle formation in the mouse skin as a consequence of radiation damage may be related to the failure to develop adnexal skin tumors.

- 5201 ANDROBLASTOMAS OF THE OVARIES INDUCED BY PENETRATING RADIATION. (Rus.) Gubareva, A. V. (Cent. Res. Inst. Roentgenol. Radiol., Leningrad, USSR). *Arkh Patol* 34(5):17-21, 1972.

Virgin hybrid mice (1663) received gamma rays in doses of 200, 600, and 900 rad at the age of 12 wk. Some of the animals were killed less than one yr after irradiation in order to study the changes in their sterilized ovaries. Most of the animals were observed until they died naturally. There were only eight androblastomas (0.3 x 0.3-1.0 x 1.0 cm) among the more than 1000 ovarian tumors induced by the penetrating radiation. The androblastomas were classified by Meyer's system as sertoliomas of the testicular tubular adenoma type (two cases) and intermediate-type androblastomas (six cases). The survival time of mice with blastomas exceeded 1 1/2 yr

postirradiation in all cases. The tumors occurred over a period of 1-1 1/2 yr. The microscopic picture of the androblastomas was not essentially different from that of human ovarian tumors. The sertoliomas were made up of numerous canals. The intermediate-type androblastomas were combinations of sarcoma-like structures and epithelioid and epithelial structures. The development of the ovarian androblastomas in mice involved the tegumental epithelium and the reticular tissue. The possibility of occurrence of androblastomas from medullary ligaments is not excluded.

5202 RADIATION LEUKEMIA IN GUINEA PIGS. (E.)

Van Pelt, A. (Biol. Div., Oak Ridge

Natl. Lab., Tenn.) and C. C. Congdon. *Radiat Res* 52(1):68-81, 1972.

The presence or absence of leukemia, and the type of leukemia, in 629 control and irradiated guinea pigs observed from 1947 through 1960 was determined by a review of records and histologic slides prepared at autopsy. Of the 48 identified cases of leukemia, 28 were lymphatic and 20 were stem cell leukemia. Statistical evidence for radiation induction of lymphatic and stem cell leukemia was found for special conditions of limited, chronic gamma-ray exposure. Stem cell leukemia was seen only in irradiated animals. In eight of the cases, including both types of leukemia, transplantation of the disease to normal syngeneic pigs was demonstrated. Unusual "reactive changes" in the white pulp of spleen and other lymphatic tissues were seen at autopsy in five animals with stem cell leukemia. The pathology findings suggest that lymphatic leukemia originates in lymph nodes and stem cell leukemia in the bone marrow.

- 5203 ELECTRON MICROSCOPIC OBSERVATIONS OF THE BEHAVIOR OF THE RAUSCHER VIRUS IN THE SPLEEN OF INFECTED MICE. (Ger.) Voigt, W.-H. (Inst. Exp. Path., Bayer AG, Wuppertal, West Germany) and H. J. Seidel. *Beitr Pathol* 145(1):1-7, 1972.

Spleens from Rauscher virus-infected BALB/c mice were examined under the light and the electron microscope in an attempt to demonstrate the presence of the virus in splenic cells other than megakaryocytes. The light microscopic observations revealed cell nests in the red spleen pulp, with enlargement and increased basophilia. Cell population was heterogeneous, however, with numerous medium-size and small cells. The electron microscopic picture, 13 days postinfection, showed extensive virus replication in megakaryocytes. Virus replication was also observed in the proerythroblasts in the greatly enlarged spleen. While Rauscher cells from erythropoietic nests proliferated intensively, virus replication in mature erythropoietic cells was rare.

- 5204 ESTABLISHMENT OF A VIRUS-PERSISTENT CELL LINE AND DERIVATION OF MALIGNANT CELL CLONES FROM RAT OSTEOSARCOMA INDUCED BY A MURINE SARCOMA VIRUS (MOLONEY). (E.) Kano-Tanaka, K. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan), T. O. Yoshida, T. Tanaka and T. Hanaichi. *Gann* 63(4):459-469, 1972.

A new cell line, designated RMS-1N, was established from a primary osteosarcoma induced in a newborn female inbred Wistar-King-Aptekman rat following injection of a murine sarcoma virus (Moloney) (MSV-M) isolate. Electron microscopic observation of early passage cells established the presence of small quantities of C-type particles. After the seventh passage (5.5 months), morphologic transformation occurred and two clonal lines, RMS-1F1 and RMS-1F2, were initiated. A third line, RMS-1F3, was initiated from the transformed RMS-1N culture after 18 months. Two additional clones, RMS-1RF-1 and -2, were established from recultivated passage 16 (13.5 months) RMS-1N cells after growth in syngenic rats. The clonal lines (except for clone RMS-1F2) consisted of rounded cells which grew actively and adhered poorly to the glass surface of the culture flask. RMS-1F1 cells were malignant and released MSV with higher infectivity than did the parental RMS-1N line. Virus released from RMS-1F1 cells was able to induce tumors in rats and in three strains of mice. The tumors (osteosarcomas in rats and myosarcomas in mice) were identical to those induced in the animals by the parental MSV-M stock. *In vitro* transformation of REWKA-2 rat cells by MSV released from RMS-1N and RMS-1F1 cells showed one-hit kinetics. A characteristic type of titration curves was that the number of foci did not decrease with the dilution factor.

- 5205 REPRESSION AND INDUCTION OF SV40 VIRUS. (Fr.) Cassingena, R. (Inst. Sci. Res. Cancer, Villejuif, France), H. G. Suarez, G. E. Sonenshein, Ch. Lavialle and Ch. Cremisi. *Bull Cancer (Paris)* 59(1):33-38, 1972.

The presence of a specific inhibitor in cells transformed by SV40 virus was investigated together with the factors responsible for the induction of SV40 viral synthesis at the time of fusion of SV40 permissive cells with transformed cells. The inhibitor was found to be a protein, since it was sensitive to trypsin and to heat, and insensitive to RNase or DNase. The action of the inhibitor during the infection of monkey cells was to reduce the viral yield; it had no effect on neoantigen synthesis, T-SV40, but inhibited about 40% of the capsule antigens of the virus. Neutralization of the inhibitor action was effected by an extract of permissive cells. In the cells transformed by SV40 and in those where no autonomous replication of viral DNA nor of viral synthesis could be detected, infectious DNA SV40 could be demonstrated by treating the cells with an extract of permissive cells to which poly-L-ornithine was added.

- 5206 DEMONSTRATION OF INFECTIOUS DEOXYRIBONUCLEIC ACID IN TRANSFORMED CELLS: I. RECOVERY OF SIMIAN VIRUS 40 FROM YIELDER AND NONYIELDER TRANSFORMED CELLS. (E.) Boyd, V. A. L. (Baylor Coll. Med., Houston, Tex.) and J. S. Butel. *J Virol* 10(3):399-409, 1972.

A new method for rescuing virus from simian virus 40 (SV40)-transformed cells is described. Deoxyribonucleic acid (DNA) extracted from virus-free SV40-transformed hamster, mouse, and monkey cells was inoculated into simian cells in the presence of diethylaminoethyl (DEAE)-dextran; infectious SV40 was recovered by using DNA from cell lines which fail to yield virus by the fusion technique as well as from cell lines which readily yield virus by fusion. The rescued virus was identified as SV40 by three methods: neutralization of plaque formation by specific antiserum; induction of synthesis of viral-specific antigens detected by immunofluorescence; and presence of papovavirus particles seen by the electron microscope. Treatment of the transformed cell DNA with deoxyribonuclease or omission of the DEAE-dextran prevented the rescue of virus. Large amounts of transformed cell DNA were required (>10 µg/culture of 10⁶ cells) to effect rescue of SV40 by passage through monkey cells. A linear response was obtained between the input of DNA with inocula between 10 and 45 µg of DNA/culture and the yield of SV40 recovered. Biological activity was demonstrable irregularly when the transformed cell DNA was assayed directly in the presence of DEAE-dextran. The DNA induced plaque formation in about 50% of the trials as well as the synthesis of SV40 tumor and viral antigens in rare simian cells. The infectious DNA appeared to be associated with cellular DNA. The infectivity was found in the pellet of precipitated DNA obtained by the Hirt technique and was inactivated by boiling for 15 min. These properties are characteristic of linear cellular DNA and not of free, circular SV40 DNA.

- 5207 ROLE OF SUBUNITS OF 60 TO 70S AVIAN TUMOR VIRUS RIBONUCLEIC ACID IN ITS TEMPLATE ACTIVITY FOR THE VIRAL DEOXYRIBONUCLEIC ACID POLY-

MERASE. (E.) Canaani, E. (Dept. Molec. Biol., U. California, Berkeley) and P. Duesberg. *J Virol* 10(1):23-31, 1972.

RNA was prepared from Prague Rous sarcoma virus (RSV), extracted with phenol and fractionated by sucrose density gradient centrifugation. Samples of 60-70S RNA were heated at 50-75 C for three min. The 60-70S RNA dissociated into 30-40S subunits and smaller RNA molecules at exposure to 55 C (the midpoint of thermal transition or T_m). When samples of 60-70S RNA were exposed to various temperatures and incubated with RSV DNA polymerase, the template activity of 60-70S RNA was lost after heating (T_m of template loss = 70 C). Analysis by velocity sedimentation and isopycnic centrifugation of the primary DNA product obtained from 60-70S RNA and RSV DNA polymerase indicated that most DNA was linked to small (<10S) RSV RNA primers. About 60% of the 60-70S RNA template activity could be recovered by incubation under annealing conditions; annealing of 30-40S subunits of 60-70S RNA did not enhance the subunits' template activity. However, in the presence of <10S subunits isolated from 60-70S RNA, the template activity of 30-40S RNA subunits was increased to the level of restored 60-70S RNA. Apparently, neither the 30-40S nor the smaller 4S subunits of the 60-70S RNA contributed as primers to the DNA template activity of 60-70S RNA, the main primer being a component of the <10S subunit fraction of 60-70S RNA.

5208 LEUKEMIA-LIKE VIRUS ISOLATED FROM A PATIENT WITH HEMOCYTOBLASTOSIS IN EXPERIMENTAL SYSTEM IN SYRIAN HAMSTERS. I. GENERAL CHARACTERISTICS OF THE DISCOVERED EXPERIMENTAL SYSTEM. (Rus.) Andzhaparidze, O. G. (Moscow Res. Inst. Viral Preparations, USSR), A. L. Liozner and L. G. Stepanova. *Vopr Onkol* 17(1):12-17, 1972.

Newborn hamster kidney cells (BHK-21) were infected with leukemia-like virus (T-9 strain, isolated from a patient with hemocytoblastosis) and were inoculated into Syrian hamsters (*Mesocricetus auratus*) s.c. and i.p. in the dose of 0.5 ml (10^6 cells/animal). On the 15-20th day, palpable tumors appeared locally on the skin in all animals (10). In 16/29 animals inoculated with the infected BHK-21 cells, large encapsulated tumor nodes were found on the peritoneal wall. A tumorigenic strain (T-BHK-IP) was obtained from these tumor nodes. Inoculation of cultures of normal human diploid cells with materials obtained after introduction of the leukemia-like virus into Syrian hamsters produced transformed cells (T-BHK-L-58-1) in the cultures. The T-BHK cells (10^4 - 10^6) were administered i.p. to hamsters immunized with the T-9 or human diploid cell cultures. Tumors did not develop in 14 hamsters receiving T-9 cells, indicating the resistance of these animals. This result shows induction of a specific antigen of the leukemia-like virus in T-BHK cells.

5209 RESISTANCE OF AKR MICE TO THE ONCOGENIC EFFECT OF THE MOUSE MOLONEY SARCOMA VIRUS. (Rus.) Tsysina, E. N. (N. F. Gamaleya Inst. Epidemiol.

Microbiol., Acad. Med. Sci. USSR, Moscow) and I. S. Irlin. *Biul Eksp Biol Med* 72(10):85-88, 1971.

The oncogenic effects of Moloney sarcoma virus on mice of various lines were studied. Moloney mouse sarcoma virus strain msv(m), 0.1-0.2 ml of various dilutions, was injected into the thigh muscles of the hind paws of mice of the lines BALB/c De, C57B1/6 and AKR and hybrid F_1 from $AKR \times C57B1/6$ and $AKR \times B61/c$ De. The virus in a dilution of 10^{-1} induced tumors in all BALB/cDe mice (30/30) and C57B1/6 mice (30/30). The virus in a greater dilution, 10^{-3} , caused tumors in 13/26 BALB/cDe mice and 6/14 C57B1/6 mice. The virus in the dose of 10^{-1} caused tumors in 27/106² AKR mice; the dilution of 10^{-2} caused no tumors in AKR mice (12). The hybrid F_1 were as sensitive to the virus as their parent mice: The virus in a dilution of 10^{-1} induced tumors in all $AKR \times C57B1/6$ F_1 (6/6) and $AKR \times BALB/cDe$ F_1 (16/16). X-ray irradiation of AKR line mice in doses 350-450 R led to a sharp decrease in their resistance to the virus; large tumors appeared in 59% (32/55) of these mice one and a half wk after the introduction of the virus. Introduction of the virus into newborn and three- to five-day-old mice led to 100% incidence of tumors in adult AKR mice. From tumors of AKR line mice induced by the virus strain msv(m) of the irradiated and young mice, virus-inducing tumors characteristic for BALB/cDe and C57B1/6 lines were isolated as well as the virus with high pathogenicity, specific for AKR line.

5210 INTRACELLULAR NUCLEIC ACID METABOLISM IN RAUSCHER'S VIRAL LEUKEMIA. (Uk.) Butenko, Z. A. (Sci. Res. Inst. Exp. Clin. Oncol., Kiev, USSR), P. P. Verkhats'kyy, A. O. Voloboyeva, D. F. Gluzman, H. Z. Nehriy, I. A. Smirnova, V. O. Shlyakhovenko and O. I. Khymenko. *Mikrobiol Zh* 34(1):58-59, 1972.

Messenger RNA (mRNA) from normal BALB/c mouse spleen cells revealed two basic and eight minor fractions upon agarose-polyacrylamide (0.5 and 3.0%, resp.) electrophoresis. Preparations from Rauscher virus-induced leukemia-altered spleen cells revealed a third major fraction in addition to the two major fractions corresponding to those of mRNA from normal mice; some of the minor fractions did not correspond to minor fractions in control preparations. Nuclear histone electrophoresis on 15% polyacrylamide gel, containing 2.5% of N,N'-methylenebis-acrylamide, revealed six main and a variable number of minor fractions in preparations obtained from normal mouse spleen cells. The histones from related leukemic mouse preparations lacked one of the less mobile fractions and presented an additional high electrophoretic mobility fraction. All major histone fractions exhibited RNase activity. Electrophoresis of cellular RNases from leukemic spleen preparations revealed an additional nuclear RNase fraction as compared to the control samples. Liver and spleen cells from leukemic mice exhibited decreased nuclear acid DNase and increased cytoplasmic acid and alkaline RNase activities as compared to normal cells. The alterations in intracellular localization and activity of nucleases in Rauscher virus-infected

mice were observed before the onset of patho-morphological symptoms of leukemia and preceded a positive immunofluorescence reaction. The latter permitted detection of a type-specific surface antigen at a later stage.

- 5211 COMPARATIVE INVESTIGATIONS ON MAMMARY TUMOR VIRUS DETECTION IN MURINE BREAST CANCER OF STRAIN CBA/B1n. (Ger.) Müller, M. (Med. Acad. Carl Gustav Carus, Dresden, East Germany), S. Zotter, H. Wagner and H. Grossmann. *Arch Geschwulstforsch* 38(3-4):221-231, 1971.

Six mammary tumors (MT) syngeneically grafted into mammary tumor virus (MTV)-bearing CBA/B1n mice were investigated for their MV content. MTV-associated antigens were determined by the indirect immunofluorescent technique on frozen cut slices and by the immunodiffusion technique (micro test) using two specific rabbit anti-MTV sera. A and B particles were detected electron microscopically on ultra-thin slices. Although these methods are not directly comparable, the results obtained by the three techniques were in relatively good agreement. As determined by immunofluorescence tests, five MT contained in a rather constant manner mutually graduated amounts of MTV-associated antigens and virus particles through succeeding transplantations generations (through the 21st generation in one tumor). In the 6th passage, one MT showed no demonstrable MTV following sarcomatous transformation. A sixth MT was free of any detectable virus in the first and second generations, though it had the characteristic histologic feature of other CBA MT. The immunofluorescent technique is recommended for rapid determination of the MTV content of MT.

- 5212 STUDIES ON MOUSE MAMMARY TUMOR VIRUS (MTV) AND MOUSE LEUKEMIA VIRUS (MuLV) BY IMMUNO-ELECTRON MICROSCOPY. (E.) Shigematsu, T. (U. Texas M. D. Anderson Hosp. Tumor Inst., Houston), L. Dmochowski and W. C. Williams. *Cancer Res* 31(12):2085-2097, 1971.

Mouse and rat cell lines which harbored type B (mouse mammary tumor virus or MTV), type C (mouse leukemia virus or MuLV) and/or type A intracytoplasmic virus particles were reacted with each of three anti-MTV rabbit antisera and with each of two anti-MuLV antisera; ferritin labeling in reaction mixtures was observed in immunoelectron microscope studies. Test cell lines included three mouse mammary tumor cell lines, a mouse reticulum cell sarcoma line and a rat bone tumor line. All three anti-MTV sera (designated Dmochowski, Nowinski and Verna) gave ferritin labeling of B particles in mouse mammary tumor lines; only Dmochowski serum stained C particles, but all three sera also stained A particles. Since the three sera were originally prepared against MTV from mice of different origins, the stained MTV were thought to contain common surface or membrane antigens. Absorption of anti-MTV sera with different antigenic material (including sheep erythrocytes,

guinea pig kidney tissue and mammary tumor-bearing mouse embryo tissue) confirmed the specificity of ferritin labeling of B particles. Two anti-MuLV sera (designated Dmochowski and Geering) gave ferritin labeling of A and C, but not of B particles in the various cell lines. MuLV particles apparently shared common surface or membrane antigens. Absorption of anti-MuLV sera with different antigenic materials confirmed the specificity of labeling of C type particles. Verna and Dmochowski anti-MTV sera showed high titers of ferritin labeling of B and A particles.

- 5213 COMPARISON OF THE STRUCTURE AND POLYPEPTIDE COMPOSITION OF THREE DOUBLE-STRANDED RIBONUCLEIC ACID-CONTAINING VIRUSES (DIPLORNAVIRUSES): CYTOPLASMIC POLYHEDROSIS VIRUS, WOUND TUMOR VIRUS, AND REOVIRUS. (E.) Lewandowski, L. J. (Stanford U. Sch. Med., Calif.) and B. L. Traynor. *J Virol* 10(5):1053-1070, 1972.

The structure and polypeptide composition of three double-stranded RNA-containing viruses, reovirus, cytoplasmic polyhedrosis virus (CPV), and wound tumor virus (WTV), were compared using the combined techniques of electron microscopy, polyacrylamide gel electrophoresis, and buoyant density centrifugation. Each of the three virus preparations could be separated into three fractions by centrifugation: 1) a rapidly migrating "major virus band" (V); 2) a somewhat slowly migrating "satellite virion band" which was deficient in some of the RNA components; and 3) a very slowly migrating "top component" composed of empty, intact shells. CPV and reovirus cores resembled each other in density ($\rho = 1.435$ and 1.440 gm/cm, resp.), ultrastructure and polypeptide composition. Both were icosahedrons and each contained numerous, regularly spaced projections which were revealed by chymotrypsin treatment. The major band and satellite band virions of both viruses showed no structural differences. Samples from each of the three bands were dissociated with urea-SDS, labeled with I^{125} , and subjected to electrophoresis. CPV was found to be composed of five polypeptides (molecular wt = 151,000, 142,000, 130,000, 67,000, and 33,000). The labeling pattern of the polyhedral bodies of CPV, which encapsulate the cores, suggested that they were composed of two major polypeptides (molecular wt = 29,500 and 19,500) and several minor components which were probably direct products of the CPV genome. WTV virions were hexagonal and did not appear to contain projections analogous to those on reovirus or CPV cores. The proteins of WTV consisted primarily of four species (molecular wt = 156,000, 122,000, 63,000, and 44,000) with several additional minor polypeptide components. These results suggested, as with CPV, that the viral proteins of WTV were coded for by messenger originating directly from the viral genome.

- 5214 SEROLOGICAL ANALYSIS OF THE DEOXYRIBONUCLEIC ACID POLYMERASE OF AVIAN ONCORNAVIRUS I. PREPARATION AND CHARACTERISATION OF MONOSPECIFIC ANTISERUM WITH PURIFIED DEOXYRIBONUCLEIC ACID POLYMERASE.

(E.) Watson, K. F. (Coll. Phys. Surg., Columbia U., New York, N.Y.), R. C. Nowinski, A. Yaniv and S. Spiegelman. *J Virol* 10(5):951-958, 1972.

Antiserum was prepared against purified DNA polymerase from the BAI strain A of avian myeloblastosis virus (AMV). Immunodiffusion assays with purified DNA polymerase showed that the anti-DNA polymerase generally formed only one precipitation band, indicating that it was monospecific. Anti-DNA polymerase showed no activity against any of the seven purified major AMV structural proteins. The antiserum showed enzyme neutralization activity which was associated with the IgG fraction. Optimal neutralizing activity was obtained with a preincubation of antiserum and polymerase for 15 min in the presence of bovine serum albumin. The antiserum showed no differences in its ability to neutralize polymerase activity directed by RNA, DNA, or RNA-DNA hybrid templates.

5215 DISTRIBUTION OF DEOXYRIBONUCLEIC ACID COMPLEMENTARY TO THE RIBONUCLEIC ACID OF AVIAN MYELOBLASTOSIS VIRUS IN TISSUES OF NORMAL AND TUMOR-BEARING CHICKENS. (E.) Baluda, M. A. (Sch. Med., U. California, Los Angeles) and W. N. Drohan. *J Virol* 10(5):1002-1009, 1972.

³H-labeled 70S ribonucleic acid (RNA) from purified avian myeloblastosis virus (AMV) was used as a probe in deoxyribonucleic acid (DNA)-RNA hybridization experiments to detect the presence of DNA complementary to the AMV genome in various tissues from noninfected normal chickens and from chickens infected with AMV. There was a remarkable constancy in the average cellular concentration of virus-specific DNA (3.3 genome equivalents/cell) found in every tissue from the same uninfected chicken, and even in different chickens from the same strain. In contrast, different tissues from chickens bearing AMV-induced kidney tumors (embryonal nephromas) revealed an unequal distribution in the average virus-specific DNA content/cell. The increase was limited to tumor cells and to tissues that contain target cells for AMV, i.e., red blood cells, kidney cells, and possibly leukocytes. The red blood cells from AMV-infected chickens suffering from acute myeloblastic leukemia, although producing no virus, contained as many viral genome equivalents/cell (about 6/cell) as did leukemic myeloblasts known to produce large quantities of AMV. An increased viral DNA content was observed in the target cells of chickens that did not show any sign of tumor formation six months after infection with AMV. This study demonstrates that vertically transmitted viral DNA is uniformly and stably distributed among all tissues of the offspring, but that horizontal infection after hatching results in an increase in viral DNA content only in some dividing, target tissues that may or may not give rise to neoplasias.

5216 SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID SYNTHESIS: THE VIRAL REPLICON. (E.) Tegtmeyer, P. (Dept. Pharmacol., Case Western Reserve U., Cleveland, O.). *J Virol* 10(4):591-598, 1972.

Temperature-sensitive (ts) mutants of SV40 (tsA7, tsA28 and tsA30) were used to infect African green monkey kidney cells and DNA production by ts mutants at 41 C was observed. The three ts mutants were deficient in DNA production at this temperature. It appeared that a host cell function could not substitute for the ts restricted virus function. Temperature-shift studies were undertaken to detect variations in kinetic characteristics of the three ts mutants and to determine the effects of temperature changes on their functions. The results indicated that the initiation of replication in the ts viruses ceased at the time of, or shortly after, temperature shifts, and that mutant replicative intermediate DNA molecules which had already been initiated before temperature shifts continued the replication process to completion. The synthesis of mutant DNA molecules themselves was initiated by a nonmutant gene product in viral complementation studies at 41 C.

5217 COMPARISON OF THE 3'TERMINI OF DISCRETE SEGMENTS OF THE DOUBLE-STRANDED RIBONUCLEIC ACID GENOMES OF CYTOPLASMIC POLYHEDROSIS VIRUS, WOUND TUMOR VIRUS, AND REOVIRUS. (E.) Lewandowski, L. J. (Dept. Molecular Biol., U. California, Berkeley) and S. H. Leppla. *J Virol* 10(5):965-968, 1972.

The 3' terminal nucleosides of the isolated components of double-stranded RNA (dsRNA) of reovirus, wound tumor virus (WTV) and cytoplasmic polyhedrosis virus (CPV) have been determined. Purified dsRNA from each virus was oxidized with periodate and reduced with ³H-labeled sodium borohydrate. The terminally labeled dsRNA genomes were then separated into their components by polyacrylamide gel electrophoresis and the labeled terminal residues were identified by paper chromatography using authentic trialcohol standards. All WTV and CPV components contained equal amounts of UOH and COH termini. The WTV components also contained small amounts of AOH and GOH termini. Reovirus components contained essentially only COH termini. Pretreatment of the viral RNAs with alkaline phosphomonoesterase did not appreciably alter either the total level or the relative amounts of ³H incorporated into the individual fractions, thus indicating that none of the three virus genomes contained phosphorylated 3'termini. It is, therefore, probable that the viral dsRNA molecules are replicated as discrete subunits.

5218 EXPERIMENTAL ALTERATION OF THE ONCOGENICITY OF FROG TUMOR CELL-VIRAL FRACTIONS. (E.) Tweedell, K. S. (Dept. Biol., U. Notre Dame, Ind.). *Proc Soc Exp Biol Med* 140(4):1246-1251, 1972.

Tissue from five spontaneous frog renal adenocarcinomas were homogenized and centrifuged to separate cytoplasmic and nuclear fractions; each fraction contained nuclear herpes-type virus (HTV). HTV-containing cytoplasmic and nuclear material was injected into frog embryos and adenocarcinoma formation was observed in adults developed from the treated embryos. Between 40-53% of embryos given cytoplasmic fractions developed renal tumors and 62% of frogs given nuclear fractions

developed renal tumors. Sonication of injected cytoplasmic or nuclear material reduced slightly the incidence of renal tumors induced by these fractions in embryos. Pretreatment of cell fractions with a proteolytic enzyme, lyophilization of these fractions before injection into embryos, or heating injected embryos (30 C), destroyed all oncogenic action of nuclear or cytoplasmic cell fraction inocula. Post-injection cooling of embryos (9 C) resulted in the formation of renal adenocarcinomas rich in intranuclear inclusions.

- 5219 COVALENT LINKAGE BETWEEN RIBONUCLEIC ACID PRIMER AND DEOXYRIBONUCLEIC ACID PRODUCT OF AVIAN MYELOBLASTOSIS VIRUS DEOXYRIBONUCLEIC ACID POLYMERASE. (E.) Verma, I. M. (Dept. Biol., Massachusetts Inst. Tech., Cambridge), N. L. Meuth and D. Baltimore. *J Virol* 10(4):622-627, 1972.

Initiation of deoxyribonucleic acid (DNA) synthesis by the avian myeloblastosis virus DNA polymerase was previously suggested to involve a ribonucleic acid (RNA) primer, the initial product being a DNA molecule joined by a phosphodiester bond to the RNA primer. The existence of such an RNA-DNA joint was investigated by assaying for transfer of a ^{32}P atom from an α - ^{32}P -deoxyribonucleotide to a 2'(3')-ribonucleotide after alkaline hydrolysis of the polymerase product. A transfer was observed, but from α - ^{32}P -deoxyadenosine triphosphate to 2'(3')-adenosine monophosphate. The transfer was seen in the endogenous AMV DNA polymerase reaction of purified virions and the reconstituted reaction of purified AMV DNA polymerase together with purified viral 60-70S RNA.

- 5220 DEOXYRIBONUCLEIC ACID POLYMERASE ACTIVITIES IN NORMAL AND LEUKOVIRUS-INFECTED CHICK EMBRYO CELLS. (E.) Weissbach, A. (Roche Inst. Molecular Biol., Nutley, N.J.), A. Bolden, R. Muller, H. Hanafusa and T. Hanafusa. *J Virol* 10(3):321-327, 1972.

DNA polymerases were studied in normal chick embryo cells, in chick cells infected with Rous-associated virus (RAV-2), and in chick cells infected with Rous sarcoma virus, type α , a noninfectious Rous virus mutant deficient in viral RNA-dependent DNA polymerase (R-DNA polymerase). The R-DNA polymerase of the RAV-2 virion could utilize (dG) $_{12}$ ·rC as a template, while the cellular R-DNA polymerase of the chick embryo cell could not copy this template under any circumstances. Chicken cells transformed by RSV α lacked detectable viral R-DNA polymerase, though cellular R-DNA polymerase was present in normal amounts.

- 5221 PREDETERMINED SEQUENTIAL CHROMOSOME CHANGES IN SERIAL TRANSPLANTATION OF ROUS RAT SARCOMAS. (E.) Mitelman, F. (Inst. Path., U. Lund, Sweden). *Acta Pathol Microbiol Scand (A)* 80(3):313-328, 1972.

Sarcoma induced in male and female inbred rats, resp., by inoculation of Schmidt-Ruppin Rous sarcoma virus, were passaged repeatedly *in vivo* and cells from different passages were examined karyologically. Cells of the female tumor initially presented normal diploid karyotypes. In passages two through seven, cells with 43 chromosomes began to appear. All these variant cells had the same karyotype. They differed from the normal cells by the loss of one St $_2$ and the gain of one St $_3$ and one large submedian chromosome. The heteroploid variant cells increased in prominence in successive passage generations. As the heteroploid cell line evolved, changes in the St $_5$ chromosome were seen. Cells of the male sarcoma showed a similar progressive change to heteroploidy. Variant cells, first seen in passages two and three, had 44 chromosomes, and differed from normal cells in having gained two t chromosomes. In both tumors, frequency of the normal diploid cells decreased with successive *in vivo* passages, but the decrease was nonlinear. In both tumors, the evolution to a heteroploid condition accompanied a progressive lack of histological differentiation.

- 5222 VIRUS DEOXYRIBONUCLEIC ACID SEQUENCES IN SUBDIPLOID AND SUBTETRAPLOID REVERTANTS OF POLYOMA-TRANSFORMED CELLS. (E.) Shani, M. (Weizmann Inst. Sci., Rehovot, Israel), Z. Rabinowitz and L. Sachs. *J Virol* 10(3):456-461, 1972.

Polyoma-transformed hamster cells which had reverted from the properties of transformed cells, while continuing to produce polyoma-specific T antigen and virus-specific RNA, were examined. These variant cells were subdiploid (with modal chromosome numbers of 39-42) or subtetraploid (modal numbers of 73-76). The number of polyoma DNA equivalents in DNA from revertants was determined and compared with that in polyoma-transformed cells (modal chromosome numbers of 44 and 45). Both transformed and revertant cells had an average of eight viral DNA copies/cell. The results indicate that duplication of chromosomes in subtetraploid revertants does not include chromosomes carrying the viral genome. Viral DNA in the revertants was associated with high-molecular wt cell DNA, as in the transformed cells.

- 5223 SYNTHETIC RNA AND DNA POLYNUCLEOTIDES: *IN VIVO* AND *IN VITRO* ENHANCEMENT OF ONCOGENESIS BY A MURINE SARCOMA VIRUS. (E.) Gazdar, A. F. (Nat'l. Cancer Inst., Bethesda, Md.) and Y. Ikawa. *Proc Soc Exp Biol Med* 140(4):1166-1169, 1972.

AL/N mice were pretreated with i.p. injections of 200 μg of one of several polyribonucleotides or polydeoxyribonucleotides 24 hr before inoculation with a preparation of Moloney murine sarcoma virus (MSV). Pretreatment with rI·rC, rA·dT, rA·rU, d(A-T), dG·dC and dT enhanced tumor induction by MSV, as demonstrated by shorter latent periods, larger mean tumor size, higher tumor incidence and longer time for complete regression. Pretreatment with calf thymus DNA, rI, rC, dA, rA·rU·rU, AMP, ATP, cAMP and dbcAMP had no effect on MSV tumor induction. Pre-

treatment with rI_rC and d(A-T) enhanced focus formation by MSV 10- 30-fold in mouse tissue cultures.

- 5224 VIRUS-LIKE PARTICLES IN METASTASES OF HUMAN MALIGNANT MELANOMA. (E.) Birkmayer, G. D. (Inst. Cell Biol., U. Munich, West Germany), B.-R. Balda, F. Miller and O. Braun-Falco. *Naturwissenschaften* 59(8):369-370, 1972.

Primary human malignant melanomas and lymph node metastases from the melanomas were examined electron microscopically for virus particles. Virus-like particles were seen in all metastatic tumors. The particles occurred only in cytoplasm and had an electron-dense nucleoid of 50-70 nm diameter and a 100 Å membrane composed of three layers.

- 5225 EPSTEIN-BARR VIRUS DNA IN HUMAN TUMOR CELLS. (Ger.) Schulte-Holthausen, H. (Inst. Virol., U. Würzburg, West Germany) and H. zur Hausen. *Zentralbl Baktériol (Orig)* 220:47-51, 1972.

Three types of tests to identify a virus with a certain type of tumor are described: the examination of tumor cells for new antigens which are tested to discover whether they are specific to a given virus, to what extent they can be induced, and the extent to which the host reacts against these viruses; and analysis of the ribonucleic acids in the tumor cells; and a direct examination of the tumor cell DNA. The attempt to demonstrate a virus-specific RNA in tumor cells was more successful in animal experiments than in human investigations, since in the former, viral genes are preferentially transcribed over the cell genome. A study using the Epstein-Barr (EB) virus was conducted based on the working hypothesis that it is a true DNA tumor virus and that it is a precursor of the Burkitt lymphoma or the Schmicke lymphoepithelioma. Labeled EB virus DNA was used in hybridization experiments with DNA from Burkitt tumor cells, as well as DNA isolated from biopsy material. It was not possible to demonstrate an EB-virus-nucleic acid sequence in Burkitt's lymphoma or a causal role for lymphoepithelioma in human tumors. However, the conclusion that EB virus can behave as a typical DNA tumor virus is warranted when test results are combined with the serological data showing the presence of viral DNA and RNA in virus particle-free cells.

- 5226 ROUS SARCOMA VIRUS NUCLEOTIDE SEQUENCES IN CELLULAR DNA: MEASUREMENT BY RNA-DNA HYBRIDIZATION. (E.) Neiman, P. E. (Dept. Med., U. Washington, Seattle). *Science* 178(4062):750-753, 1972.

RNA from Prague strain Rous sarcoma virus (Pr RSV) was hybridized with excesses of DNA from Pr RSV-induced chicken sarcoma cells or with excess DNA from normal chick embryo cells. The 71S Pr RSV RNA fraction was used. Most of the viral 71S genome was present in DNA of virus-induced sarcoma cells; a major fraction had a very low frequency/cell. One

third of the viral RNA reacted with at least partially complementary cellular DNA with kinetics suggesting an average of 100 copies of these DNA sequences/cell. Normal chick embryo DNA contained sequences at least partially homologous to some fraction of Pr RSV RNA.

- 5227 SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID SYNTHESIS: ANALYSIS BY GEL ELECTROPHORESIS. (E.) Tegtmeyer, P. (Dept. Pharmacol., Case Western Reserve U., Cleveland, O.) and F. Macasaet. *J Virol* 10(4):599-604, 1972.

SV40 DNA labeled with ¹⁴C-thymidine was extracted from purified virions and subjected to electrophoresis through 2% agarose gels. Accurate estimates of the relative quantities of radiolabeled DNA I, DNA II and DNA replicative intermediate molecules (RI) could be made using this method of analysis. RI molecules in different stages of the replication process could be identified, given the assumption that RI molecules in early stages of the replication process migrate more slowly than DNA I, while RI in later stages migrates more slowly than DNA II.

- 5228 RAPID IMMUNOLOGICAL INDUCTION OF MURINE LYMPHOMAS: EVIDENCE FOR A VIRAL ETIOLOGY. (E.) Cornelius, E. A. (Yale U. Sch. Med., New Haven, Conn.). *Science* 177(4048):524-525, 1972.

A graft-versus-host reaction (GVHR) was induced in 16 (SJL/J x C57BL/1)F₁ hybrid mice by five weekly i.p. injections of spleen cells from SJL/J mice. All mice given spleen cells developed reticulum cell sarcomas which involved spleen, lymph nodes, liver and lungs but not thymus. Tumors from the hybrid mice could be transplanted to syngeneic hybrid recipients. Tumors from hybrid donors also grew on C57BL/1 recipients, but not on SJL/J, (NZB x SJL/J)F₁ or NZB recipients. This indicated that the sarcomas induced by the GVHR were antigenically C57BL/1. Since both SJL/J and C57BL/1 mice carry tumorigenic viruses, viruses were thought to be implicated in the immunological induction of these tumors.

- 5229 A REPLICATING RNA MOLECULE SUITABLE FOR A DETAILED ANALYSIS OF EXTRACELLULAR EVOLUTION AND REPLICATION. (E.) Kacian, D. L. (Coll. Phys. Surg., Columbia U., New York, N.Y.), D. R. Mills, F. R. Kramer and S. Spiegelman. *Proc Nat Acad Sci USA* 69(10):3038-3042, 1972.

In examining the products of Q β phage RNA-directed RNA polymerase, one variant RNA replicase molecule (MDV-1) was singled out. It was 218 nucleotides long and had a strand structure consisting of an anti-parallel complementary duplex. The MDV-1 replicase molecule replicated in a manner similar to phage Q β RNA, and could mutate to previously determined phenotypes. The MDV-1 molecule was suitable for study of RNA replication.

- 5230 STRUCTURAL PROTEINS OF SIMIAN VIRUS 40: PHOSPHOPROTEINS. (E.) Tan, K. B. (Wistar Inst. Anatomy Biol., Philadelphia, Pa.) and F. Sokol. *J Virol* 10(5):985-994, 1972.

The structural proteins of purified SV40 were analyzed by polyacrylamide gel electrophoresis following labeling of infected secondary African green monkey cultures with ^{32}P -orthophosphate and ^3H -amino acids. All five SV40 structural proteins were phosphorylated. The ^{32}P was not present as an acylphosphate. No phosphohistidine was detected. Alkaline phosphatase treatment resulted in a significant dephosphorylation of and an increase in the heterogeneity in the molecular size of viral polypeptide I but had no effect on the other viral polypeptides. All five proteins were degraded by NaOH or pronase. The results indicated that the main polypeptide (#1, molecular wt = 49,000) of SV40 contained o-phosphoserine and/or o-phosphothreonine residues; however, the nature of the bond between phosphate and the other viral peptides remained obscure. The proteins of "empty" virus, which contains little or no DNA, showed phosphorylation patterns similar to infectious virus. Neither empty virus particles nor infectious virus was able to stimulate incorporation of ^{32}P -orthophosphate into protein, indicating that SV40 lacks its own protein kinase.

- 5231 ORIGIN AND DIRECTION OF SIMIAN VIRUS 40 DEOXYRIBONUCLEIC ACID REPLICATION. (E.) Fareed, G. C. (Natl. Inst. Allergy Infect. Dis., Bethesda, Md.), C. F. Garon and N. P. Salzman. *J Virol* 10(3):484-491, 1972.

Replicating SV40 DNA molecules fractionated on the basis of extent of replication were examined. Double-labeled replicating DNA molecules from SV40 were prepared and cleaved by the replicative intermediate (R_1) restriction endonuclease from *E. coli*. The site of cleavage on the replicating DNA molecule was used to position the origin of replication on the molecule and the two branch points. Analysis of cleavage products was performed by velocity gradient centrifugation on neutral and alkaline sucrose as well as by electron microscopy. The R_1 cleavage site was 33% of the genome length from the origin of replication. Both branch points were growing points. The results indicate that the origin of SV40 DNA replication is specific and the orientation is bidirectional.

- 5232 ISOLATION OF TEMPERATURE-SENSITIVE MUTANTS OF MURINE SARCOMA VIRUS. (E.) Scolnick, E. M. (Natl. Cancer Inst., Bethesda, Md.), J. R. Stephenson and S. A. Aaronson. *J Virol* 10(4):653-657, 1972.

Kirsten murine sarcoma viruses mutagenized by bromodeoxyuridine or azacytidine were used to infect mouse cells. Three temperature-sensitive (ts) mutant virus cell lines were recovered from the infected cells. The ts mutants did not spontaneously release

virus and did not show murine or rat viral group-specific antigens when grown at 39-40 C. The temperature sensitivity of the transformed morphology of the three ts mutant lines was due to temperature sensitivity of a viral rather than a cellular gene product. The ts mutant virus-transformed cells formed colonies on cell monolayers at 32 C but not at 39-40 C. Superinfection with Kirsten virus restored colony-forming ability at 39-40 C in one of the three ts mutant lines.

- 5233 ABSENCE OF POLYMERASE PROTEIN IN VIRIONS OF ALPHA-TYPE ROUS SARCOMA VIRUS. (E.)

Hanafusa, H. (Publ. Hlth. Res. Inst., New York, N.Y.), D. Baltimore, D. Smoler, K. F. Watson, A. Yaniv and S. Spiegelman. *Science* 177(4055):1188-1191, 1972.

Noninfectious α -type Bryan strain Rous sarcoma virus (RSV α), derived from RSV-transformed chicken cells, was examined for DNA polymerase with different template-primer complexes. No DNA polymerase could be demonstrated in RSV α in assays with poly(A) \cdot oligo(dT), poly(C) \cdot oligo(dG) or poly(A) \cdot poly(dT). In related experiments, RSV α was tested for its ability to absorb antibody from a monospecific rat anti-avian myeloblastosis virus DNA polymerase antiserum. RSV α was negative in this test, indicating that the virus does not even contain DNA polymerase as a latent but immunologically active protein.

- 5234 SEROLOGICAL ANALYSIS OF THE DEOXYRIBONUCLEIC ACID POLYMERASE OF AVIAN ONCORNAVIRUSES II. COMPARISON OF AVIAN DEOXYRIBONUCLEIC ACID POLYMERASES. (E.) Nowinski, R. C. (McArdle Lab. Cancer Res., U. Wisconsin, Madison), K. F. Watson, A. Yaniv and S. Spiegelman. *J Virol* 10(5):959-964, 1972.

Monospecific antiserum prepared against the isolate DNA polymerase of avian myeloblastosis virus (AMV) was used to study the RNA-directed DNA polymerase activity of several detergent-disrupted C-type viruses. The antiserum was able to neutralize the RNA-directed DNA polymerase activity of all avian leukemia-sarcoma viruses tested irrespective of viral antigenic subtype. The DNA polymerase activity of avian reticuloendotheliosis virus and of a variety of mammalian oncornaviruses was not affected by antipolymerase antiserum. The anti-polymerase antiserum showed no activity against the seven major structural AMV proteins or normal cellular DNA polymerases. The RSV $\alpha(0)$ mutant, which lacks DNA polymerase activity, showed a 60-fold decrease in the demonstrable polymerase antigen level. Indirect immunofluorescence studies showed that the viral polymerase was a cytoplasmic constituent of virus-producing chicken cells. Polymerase antigen was absent in uninfected chicken cells.

- 5235 LOSS OF SIMIAN VIRUS 40 DNA-RNA HYBRIDS FROM NITROCELLULOSE MEMBRANES: IMPLICATIONS FOR THE STUDY OF VIRUS-HOST DNA INTERACTIONS. (E.)

Haas, M. (Salk Inst., San Diego, Calif.), M. Vogt and R. Dulbecco. *Proc Nat Acad Sci USA* 69(8):2160-2164, 1972.

SV40 viral DNA, isolated from monkey cells infected with SV40 at high and low multiplicities of infection, was hybridized with SV40 complementary RNA (cRNA). Hybridization mixtures were incubated for 16-18 hr and maintained on nitrocellulose membranes. Extensively hybridized DNA was not retained by the membranes; the amount of viral DNA retained by membranes dropped rapidly, especially with DNA from cells infected at high SV40 multiplicities. The loss of DNA-RNA hybrid molecules was not prevented by addition of hamster or *E. coli* DNA to incubation mixtures. SV40-transformed hamster cell DNA-RNA hybrids were retained on membranes if DNA fragments were relatively long. They were not retained if DNA fragments were sheared to 100,000 daltons/single strand (less than the length of the SV40 DNA molecule). Apparently, each of the six genomes/cell in SV40-transformed cells was individually integrated.

5236 TRANSMISSION OF LYMPHOSARCOMA FROM CATTLE TO SHEEP. (E.) Olson, C. (Dept. Vet. Sci., U. Wisconsin, Madison), L. D. Miller, J. M. Miller and H. E. Hoss. *J Nat Cancer Inst* 49(5):1219-1480, 1972.

Thirteen one- to two-week-old lambs were inoculated with cultured lymphocytes from a spontaneous, C-type virus-producing lymphosarcoma from a 2.5-year-old cow. Sixteen other lambs were inoculated with material from a generalized, C-type virus-negative lymphosarcoma from a six-month-old cow. Eleven of the 13 lambs given lymphocytes from adult-type bovine lymphosarcoma became infected with C-type bovine virus. Five of the 13 died of lymphosarcoma in 24 1/2-27 1/2 months. All five sheep dying from lymphosarcoma had lymphoid tumor involving thymic tissue. One had fibroblastoma in lymphosarcomatous thymic tissue; another had skin lesions composed of an infiltrating mass of neoplastic lymphoid cells. Only one of the 16 sheep given cells from juvenile lymphosarcoma developed C-type virus infection.

5237 INTRACRANIAL FIBROBLASTIC NEOPLASMS IN THE HAMSTER FROM BOVINE PAPILLOMA VIRUS. (E.) Robl, M. G. (Dept. Vet. Sci., U. Wisconsin, Madison), D. E. Gordon, K. P. Lee and C. Olson. *Cancer Res* 32(10):2221-2225, 1972.

Twenty-four hamsters were inoculated in the right cerebral hemisphere with a suspension of bovine papilloma virus (BPV) prepared from a bovine fibropapilloma. Ten other hamsters were inoculated with BPV heated at 92° for 30 min. Intracranial tumors developed in 16 of 19 surviving hamsters given untreated BPV; meningeal tumors were evident in these hamsters by 30 days postinoculation. These tumors invaded the adjacent brain via the vascular system. Intracranial tumor cells did not contain virus particles; the tumors were made up of immature active fibroblasts. Fibroblasts of the cranial

cavity and subcutis were more susceptible to tumorigenesis by BPV than were other fibroblasts. No hamsters inoculated with heat-treated BPV developed tumors.

5238 EARLY REPLICATION OF HERPESVIRUSES IN NATURALLY OCCURRING FROG TUMORS. (E.)

McKinnell, R. G. (Dept. Zool., U. Minnesota, Minneapolis), V. L. Ellis, D. C. Dapkus and L. M. Steven, Jr. *Cancer Res* 32(8):1729-1733, 1972.

Fifteen renal adenocarcinomas were collected from leopard frogs in Kandiyohi County, Minnesota, prior to and 4, 7, 13 and 16 days after entry of host frogs into lakes for winter hibernation. Each tumor was fixed and thin sections were observed under the electron microscope for the presence of herpesvirus. No virus particles were seen in the four tumors from prehibernating frogs or in the two tumors from frogs autopsied on day four of overwintering. Mature herpesviruses were observed in two tumors of frogs that had been in the water for seven days. Three of seven tumors from frogs in the water for more than seven days contained no detectable virus particles. All tumors from frogs which had been in the water for over one month contained herpesviruses. Since oocytes and sperm cells are fully formed at the time mature, tumor-bearing frogs enter lakes for overwintering, the gametes are potentially exposed to mature viruses throughout the overwintering period. This could enable vertical transmission of herpesviruses.

5239 GROWTH OF ROUS SARCOMAS IN BURSECTOMIZED CHICKENS. (E.) McArthur, W. P. (New York U. Med. Ctr., N.Y.), E. A. Carswell and G. J. Thorbecke. *J Nat Cancer Inst* 49(3):907-909, 1972.

Chickens were bursectomized before hatching or shortly after hatching; by four to five wk of age, bursectomized birds were demonstrably hypogammaglobulinemic or agammaglobulinemic with respect to IgG and IgM. When injected with Bryan Rous sarcoma virus (10^{-3} - 10^{-5} dilution), bursectomized chickens showed an incidence of sarcoma development similar to that shown by unbursectomized normal birds. Tumor growth was also similar in the two groups. The results suggest that "blocking" or "enhancing" antibodies are not essential for growth of Rous sarcoma.

5240 DIFFERENTIAL ENHANCEMENT OF R-TYPE VIRUS PARTICLES IN POLYOMA-TRANSFORMED BHK-21 CELLS BY DIMETHYL SULFOXIDE. (E.) Kisch, A. L. (U. New Mexico Sch. Med., Albuquerque), R. O. Kelley and B. J. Eberle. *J Nat Cancer Inst* 49(3):911-914, 1972.

R-type virus particles (RTP) were examined by electron microscopy in untransformed hamster fibroblasts (BHK-21) and in a cloned line (Cl-1) of BHK-21 cells transformed by polyoma virus. Significantly more RTP were seen in Cl-1 cells than in BHK-21 cells, five

BHK-21 cells having two or more RTP, and 14 Cl-1 cells having two or more RTP. Propagation in medium containing 2% (v/v) dimethyl sulfoxide increased the number of RTP in Cl-1 cells but not in BHK-21 cells. The results suggest that RTP may interact with DNA viruses in the induction, maintenance or expression of functional alterations associated with cell transformation.

- 5241 COMPOSITION AND SIZE OF SHOPE FIBROMA VIRUS DEOXYRIBONUCLEIC ACID. (E.) Jacquemont, B. (Natl. Inst. Hlth. Med. Res., Lyon, France), J. Grange, L. Gazzolo and M. H. Richard. *J Virol* 9(5):836-841, 1972.

Rabbit kidney cells were inoculated with Shope fibroma virus (SFV) and labeled with ^3H - or ^{14}C -thymidine; SFV DNA was extracted from infected cells and its composition and size were calculated. Buoyant densities of cellular DNA, SFV DNA and vaccinia virus DNA were determined by analytical centrifugation in CsCl gradients, *M. lysodeikticus* DNA being used as a density marker. SFA DNA had a density of 1.6696 ± 0.0003 g/ml, similar to that of cellular DNA; vaccinia virus had a density of 1.6948 ± 0.004 g/ml. Guanine plus cytosine content values (G + C) calculated from these densities were 40.9 ± 0.4 for cellular DNA, 40.4 ± 0.3 for SFV DNA and 35.5 ± 0.4 for vaccinia virus. When SFV virions were treated with Pronase and detergent and cosedimented in sucrose density gradients, the molecular wt of SFV DNA was found to be 153×10^6 daltons. Only one of 65 SFV DNA molecules appeared to have this molecular wt under the electron microscope; the length average for SFV DNA was 49.8 ± 0.9 μm .

- 5242 OBSERVATIONS ON SUCCESSIVE GENERATIONS OF TUMORS PRODUCED IN HAMSTERS BY INOCULATION OF SV40-TRANSFORMED CELLS. (E.) Menezes, J. (Fac. Med. U. Ottawa, Ontario, Canada). *Tumori* 58:95-106, 1972.

SV40-transformed hamster cells, inoculated s.c. into hamsters, produced sarcomas in all of 90 five wk old recipients and in 95% of 40 15 wk old recipients. These tumors developed within three to 20 wk post-inoculation, and frequently metastasized to lymph nodes. Tumor cells which had undergone successive passages *in vivo* were more likely to produce metastasizing tumors on inoculation into recipients. Two other factors were associated with metastatic potential of tumor cell inocula: increased capacity of tumor cells for fusion, and increased number of polykaryocytes in tumor cell cultures. The percentages of polykaryocytes in tumor cell cultures increased in successive *in vivo* generations; however, the polykaryocytes appeared not to multiply, for their numbers decreased in *in vitro* passages. Polykaryocytes died or became drastically reduced in number in tumor cells which were frozen, centrifuged or trypsinized. Rescuability of SV40 and presence of T antigen persisted in tumor cells passaged *in vivo*.

- 5243 ELECTRON MICROSCOPIC STUDIES OF REPLICATING SV40 DNA. (E.) Yamamoto, S. (Okayama U. Med. Sch., Japan) and T. Oda. *Acta Med Okayama* 25(4):237-243, 1971.

VERO monkey cells were infected with SV40 and SV40 DNA was extracted and subjected to equilibrium density gradient centrifugation on CsCl. Fraction 17 on the CsCl gradient contained twisted or open circular DNA molecules, circular molecules with two branch points (θ form DNA), and circular molecules with a single tail (σ form DNA). θ and σ form DNA molecules were thought to represent replicating SV40 DNA, and were examined under the electron microscope. θ and σ DNA comprised 8.9% and 4.3% of all viral DNA, resp. at 54 hr after infection. Of 16 σ form DNA molecules, 11 had rings of viral DNA length and five had rings twice this length. The replication rate of these molecules ranged from 10% to 95%. The smallest molecule of replicating SV40 DNA observed was 1 μ in contour length.

- 5244 EXPRESSION OF THE SARCOMA GENOME IN A ROUS MOUSE TUMOR CELL LINE, SR-C3H-2127. (E.) Hino, S. (Inst. Med. Sci., U. Tokyo, Japan) and T. Tamamoto. *Cann* 62(6):539-544, 1971.

Cells of the line SR-C3H-2127, derived from a C3H mouse ascites tumor induced by Schmidt-Ruppin Rous sarcoma virus (SR-RSV), were fused with chicken embryo cells. Other chicken cells were infected with the supernatant of the fusion culture medium. The procedure permitted rescue of the SR-RSV genome from the SR-C3H-2127 cells. SR-C3H-2127 itself produced a murine C-type RNA virus (2127). This virus could infect DDD mouse embryo cells, but could not infect chicken cells. Cell fusion studies showed that there was no phenotypic mixing between the SR-RSV genome and the murine C-type virus. Active transport of 2-deoxy-D-glucose was observed in SR-C3H-2127 cells, and compared with that seen in a contact-inhibition-sensitive, murine leukemia virus-free, 2127 virus-infected cell line (C3H2K). Glucose transport was accelerated in SR-C3H-2127 cells but not in C3H2K cells. This confirmed the expression of the SR-RSV genome in SR-C3H-2127 cells.

- 5245 MURINE LEUKEMIA VIRUS: RESTRICTION IN FUSED PERMISSIVE AND NONPERMISSIVE CELLS. (E.) Tennant, R. W. (Oak Ridge Natl. Lab., Tenn.) and C. B. Richter. *Science* 178(4060):516-518, 1972.

Human WI38 cells, which were nonpermissive for Moloney leukemia virus replication, were fused with inactivated Sendai virus and exposed to Moloney virus. Moloney virus replication could not be detected, nor were typical C-type virus particles visible intracellularly. When Moloney virus was used to infect heterokaryons produced by fusion of WI38 cells with permissive 3T3 mouse cells, virus synthesis was still absent, though 3T3 synkaryons were permissive for virus synthesis. When clones of human mouse hybrid cells, produced by fusing KL strain human cells and

BT3-43 mouse cells, and lacking as much as half the human chromosome complement, were infected with Moloney virus, all clones were permissive. This suggested that the nonpermissive state of human cells was due to a gene functioning as a director of a repressor of mouse leukemia replication.

5246 RAPID IMMUNOLOGICAL INDUCTION OF MURINE LYMPHOMAS: EVIDENCE FOR A VIRAL ETIOLOGY. (E.) Cornelius, E. A. (Yale U. Sch. Med., New Haven, Conn.). *Science* 177(4048):524-525, 1972.

A graft-versus-host reaction was produced in (SJL/J x C57BL/1)F₁ mice (SB)F₁ by five weekly injections i.p. of spleen cells from SJL/J mice. By 40 wk post-injection, all recipients had developed reticulum cell sarcomas in spleen, lymph nodes, liver and lungs. Tumors from eight mice were transplanted by i.p. injection into mice of the following strains: (SB)F₁, SJL/J, C57BL/1, (NZB x SJL/J)F₁ and NZB. Tumor implants grew only in (SB)F₁ and C57BL/1 mice. Since SJL/J and C57BL/1 mice carry tumorigenic virus, the evidence suggests a viral etiology for the tumors, which were antigenically C57BL/1.

5247 NUCLEOTIDE COMPOSITION OF THE RNA FROM RD-114 VIRIONS. (E.) Roy-Burman, P. (U. Southern California Sch. Med., Los Angeles) and M. B. Kaplan. *Biochem Biophys Res Commun* 48(6):1354-1361, 1972.

RNA was extracted from two feline viruses: RD-114, virus released from a human rhabdomyosarcoma cell line (RD) which was virus-free until passaged through a fetal cat; and RD-FeLV, released from RD cells after infection with Gardner-Arnstein feline leukemia virus (FeLV). RNA was layered onto a linear 5-20% sucrose gradient and centrifuged to yield a 4S and a 70S fraction. These RNA fractions were subjected to enzymatic hydrolysis and their nucleotide compositions were studied by chromatography. Minor nucleotides were seen in 4S RNA only. This RNA contained 5,6-dihydro-UMP and pseudo-UMP as minor nucleotides. The base compositions of RD-114 and RD-FeLV were different; the former virus resembled strain 5 FeLV in base composition.

5248 CHANGES IN ACYL GROUP COMPOSITION OF PHOSPHOLIPIDS FROM CHICKEN EMBRYONIC FIBROBLASTS AFTER TRANSFORMATION BY ROUS SARCOMA VIRUS. (E.) Yau, T. M. (Cleveland Psychiat. Inst., Ohio) and M. J. Weber. *Biochem Biophys Res Commun* 49(1):114-120, 1972.

Phospholipids isolated from normal chicken embryo cells and from cells infected with Schmidt-Ruppin Rous sarcoma virus (RSV) were analyzed by gas-liquid chromatography. Each of the phospholipids analyzed showed acyl group specificity. Significant differences in acyl group composition were also seen in individual phospholipids isolated from untransformed

and RSV-transformed cells. Specifically, arachidonate was decreased in transformed cells while oleate was increased.

5249 GROWTH OF WOUND TUMOR VIRUS IN VECTOR CELL MONOLAYERS. (E.) Kimura, I. (Dept. Botany, U. Illinois, Urbana) and L. M. Black. *Virology* 48(3):852-854, 1972.

Vector cell monolayers from *Agallia constricta* were inoculated with preparations of wound tumor virus (WTV), a plant virus, and the appearance of transformed foci was observed. Foci first appeared in monolayers four hr after inoculation; the number of foci increased exponentially from 4-14 hr and leveled off between 14-22 hr. When the virus content of infected monolayers was determined by assaying the infectivity of infected monolayers, the doubling time for WTV was found to be about 58 min between 6-12 hr after inoculation.

5250 ACTIVATION OF C-TYPE RNA VIRUS MARKERS IN THE MOUSE UTERINE TISSUE. (E.) Fowler, A. K. (Natl. Cancer Inst., Bethesda, Md.), C. D. Reed, G. J. Todaro and A. Hellman. *Proc Natl Acad Sci USA* 69(8):2254-2257, 1972.

The effects of natural (estradiol-17 β) and synthetic steroidal estrogens, synthetic nonsteroidal [diethylstilbestrol and dichlorodiphenyltrichloroethane (DDT)] estrogenic compounds, and whole-body irradiation (1000 and 5000 rad) were studied on the *in vivo* activation of two C-type RNA virus markers in the uteri of ovariectomized adult NIH Swiss Mice. *In vitro* complement fixation assays, Ouchterlony diffusion tests and C-type virus-specific RNA-directed DNA polymerase assays were able to detect group-specific viral antigen and RNA-directed DNA polymerase within four days after stimulation. Uterine hypertrophy was not a prerequisite for viral antigen expression and the response was not accompanied by an increase in protein concentration. The hormonal and X-irradiation-induced activation of virus marker expression may represent two physiological means of viral genome derepression.

5251 PRESENCE OF VIRUS-SPECIFIC RNA IN HAMSTER CELLS TRANSFORMED BY SIMIAN ADENOVIRUS SA7: BRIEF REPORT. (E.) Mäntyjärvi, R. A. (Milton S. Hershey Med. Ctr., Pennsylvania State U., Hershey). *Arch Gesamte Virusforsch* 37(2/3):288-292, 1972.

Three lines of hamster cells transformed *in vitro* by simian adenovirus 7 (SA7) and one line derived from an SA7-induced hamster tumor were used in RNA-DNA hybridization tests to determine the presence of SA7-specific RNA in transformed hamster cells. Binding of RNA from SA7 to DNA from SA7 was 2.2-4.4 times higher than binding of SA7 RNA to DNA from untransformed control cells. This indicated that virus-specific RNA was present in the SA7-transformed hamster cells.

- 5252 INDUCTION OF INTRACRANIAL TUMORS IN MICE BY HUMAN ADENOVIRUS TYPE 12. II. ENHANCEMENT BY N,N'-DIMETHYLNITROSOUREA. (E.) Murao, T.. (Okayama U. Med. Sch., Japan). *Acta Med Okayama* 25(4):261-268, 1971.

C₃Hf/Bi (Zb) mice were divided into three groups and treated as follows: 27 mice inoculated intracranially with 0.015 ml fluid preparation of adenovirus type 12 (group 1); 23 mice inoculated with virus and ten days later inoculated s.c. with 20 mg/kg N,N'-dimethylnitrosourea (group 2); 18 mice inoculated s.c. with the carcinogen alone (group 3). Intracranial tumors developed in 12 of 25 surviving mice in group 1, in 19 of 21 group 2 survivors and in none of group 3 mice. Latent periods averaged 124 days for group 1 mice and 108 days for group 2 mice. Most tumors were made up of spindle-shaped cells arranged irregularly with scanty stroma.

- 5253 SPONTANEOUS PRODUCTION OF MURINE TYPE C VIRUS PARTICLES BY MOUSE ROUS SARCOMA CELLS AFTER LONG-TERM *IN VITRO* CULTIVATION. (E.) Oda, T. (Okayama U. Med. Sch., Japan), N. Yamaguchi and T. Yamamoto. *Gann* 62(6):535-538, 1971.

Electron microscopic observations revealed that a long-term cultured clonal cell line from an ascites sarcoma of C₃H/He mice induced by chicken Rous sarcoma cells spontaneously produced murine C-type virus particles. The cells contained no demonstrable Rous sarcoma virus (RSV) but did not contain RSV genome in a form transmissible to chicken cells. While the virogene of the murine C-type virus may have been present originally in the mouse ascites sarcoma cells, the oncogene of the cultured cells was not associated with the virogene but with the RSV genome.

- 5254 INCIDENCE OF SPONTANEOUS NEOPLASMS IN BREEDING AND RETIRED BREEDER BALB/cCr MICE THROUGHOUT THE NATURAL LIFE SPAN. (E.) Peters, R. L. (Microbiol. Assoc., Inc., Walkersville, Md.), L. S. Rabstein, G. J. Spahn, R. M. Madison and R. J. Huebner. *Int J Cancer* 10(2):273-282, 1972.

Approximately 1300 weaning to 10-month-old (breeders) BALB/cCr mice and 4500 10- to 12-month-old (retired breeders) BALB/cCr mice were observed throughout the remainder of their natural life span to determine age-specific incidence of various spontaneous neoplasms. Over 2000 mice were necropsied and their tissues examined microscopically. In general, neoplasms of all types were rare in animals younger than one yr; however, an early life "peak" (one to six months) of acute lymphocytic leukemia was observed. After 23 months, lymphocytic neoplasms decreased in frequency and the incidence of reticulum cell tumors increased progressively. No cases of myelocytic or stem cell leukemias were observed. No epithelial tumors were diagnosed prior to seven months. From seven to 19 months most epithelial tumors were mammary adenocarcinomas or myoepitheliomas. Beyond

this age, other epithelial tumors, especially pulmonary alveologenic adenocarcinomas, predominated. Mesenchymal tumors, which were seen after six months of age, were most frequently hemangioendotheliomas located in the vessels of the liver, uterus, and ovaries. No benign tumors were observed prior to ten months of age after which time alveologenic adenomas of the lung were the most frequent. The frequencies of all neoplasms other than lymphatic increased progressively with age. Of 24 mice with multiple primary malignancies, six had multiple nonlymphomatous solid tumors, two had multiple hematopoietic type neoplasms, and the remainder had combinations of lymphatic or reticulum cell tumors and non-lymphomatous solid malignancies.

- 5255 SYNTHESIS OF TUMOUR ANTIGEN AND CHANGES IN ACTIVITIES OF GLYCOLYTIC ENZYMES INDUCED BY POLYOMA VIRUS. (E.) Guminska, M. (Med. Acad., Cracow, Poland) and Z. Porwit-Bobrz. *Acta Virol (Praha)* 16(3):183-190, 1972.

Titers of tumor (T) antigen and activities of hexokinase (HK), pyruvate kinase (PK), phosphofructokinase (PFK) and lactate dehydrogenase (LDH) were determined in primary cultures of mouse embryo (ME) cells and BHK 21 cells infected with polyoma virus. In the early phase of infection of both cell systems, polyoma virus-induced synthesis of T antigen resulted in changed activities of the glycolytic enzymes. In ME cells, the activities of HK, PFK, PK and LDH increased simultaneously following infection. In BHK 21 cells, only HK, PK and LDH activities increased at the onset of infection. PFK activity did not increase until four days postinfection. The activities of all enzymes dropped sharply in ME cells during the cytolytic phase of infection. Following a drop in activity 5-9 days postinfection, HK, PK and LDH showed a second stable rise of activity in BHK cells 7-14 days postinfection. PFK continued to increase gradually but steadily in BHK cells throughout the observation period. T antigen synthesis dropped during cytolytic interaction in ME cells but was continuous in the late phase of infection of BHK 21 cells.

- 5256 THETA PARTICLES: A STRUCTURE FOUND IN HAMSTER SARCOMA VIRUS. (E.) Albino, A. P. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.), E. DeHarven and F. K. Sanders. *J Virol* 10(3):477-483, 1972.

Hamster sarcoma virus (HaSV), a newly isolated RNA tumor virus, was pelleted directly from tissue cultures of hamster cells into a capsule for electron microscopic examination. Under these circumstances, HaSV consisted of C-type particles. When HaSV was concentrated by polyethylene glycol or ammonium sulfate followed by density gradient banding, 30-40% of particles were not of the C-type morphology. These particles appeared as enveloped structures each containing a flattened core resembling the Greek θ . Cores of θ particles were in the form of flattened discs assumed to contain

RNA. Similarly treated feline leukemia virus and Rauscher murine leukemia virus did not show 0 particles.

- 5257 REVERSIBLE INACTIVATION OF DEOXYRIBONUCLEIC ACID POLYMERASE OF RAUSCHER LEUKEMIA VIRUS. (E.) Tronick, S. R. (Natl. Cancer Inst., Bethesda, Md.), E. M. Scolnick and W. P. Parks. *J Virol* 10(4):885-888, 1972.

DNA polymerase was isolated from Rauscher murine leukemia virus (RMuLV) and exposed to 6 M guanidine hydrochloride (GuHCl). RMuLV DNA polymerase exposed to GuHCl lost all detectable activity. Enzyme activity was restored by removing GuHCl by dialysis in the presence of Triton X-100. RMuLV DNA polymerase was studied by gel filtration on agarose equilibrated with 6M GuHCl. The viral RNA-directed DNA polymerase had a molecular wt of 70,000 and evidently consisted of a single polypeptide chain.

- 5258 GENETIC MAPPING OF A MURINE LEUKEMIA VIRUS-INDUCING LOCUS OF AKR MICE. (E.) Rowe, W. P. (Natl. Inst. Allergy Infect. Dis., Bethesda, Md.), J. W. Hartley and T. Bremner. *Science* 178 (4063):860-862, 1972.

The chromosomal location of one of the two murine leukemia virus-inducing loci of AKR mice was determined. Analysis of the locus was facilitated by its isolation in backcross generations (e.g., C57BR (C57BR x AKR) F_1). The locus was located on linkage group I, as was the locus for isozymes of glucose phosphate isomerase (*Gpi-1*). There was close linkage between the virus-inducing locus (designated *Akv-1*) and *Gpi-1*; the two loci were 12 map U apart. Gene order was *c-Gpi-1-Akv-1*.

- 5259 RABBIT KIDNEY VACUOLATING VIRUS IN SPONTANEOUS SHOPE PAPILLOMAS OF COTTONTAIL RABBITS. (E.) Goldman, P. M. (Milton S. Hershey Med. Ctr., Hershey, Pa.), C. M. Lang and J. W. Kreider. *J Nat Cancer Inst* 49(5):1277-1281, 1972.

Papillomas were excised from rabbits and examined for the presence of Shope papilloma virus (SPV) and rabbit kidney vacuolating virus (RKV). Of 18 spontaneous papillomas, six contained both viruses, five contained SPV, three contained RKV and four contained neither virus. Immunofluorescent SPV antigen was found in the nuclei of papilloma cells; SPV antigen was localized similarly in all papillomas, regardless of the presence or absence of RKV. No papillomas contained RKV antigen, despite the fact that rabbit kidney tissue culture cells infected *in vitro* with RKV stained readily with anti-RKV antibody. Titers of SPV in papillomas with recoverable SPV and in papillomas with both SPV and RKV were similar. There was no correlation

between papilloma morphology and presence or absence of either virus.

- 5260 IMMUNE RESPONSE IN THE HAMSTER: VI. ANTIBODY RESPONSE IN POLYOMA ONCOGENESIS. (E.) Coe, J. E. (Natl. Inst. Allergy Infect. Dis., Hamilton, Mont.) and K. K. Takemoto. *J Nat Cancer Inst* 49(1):39-44, 1972.

Sera were obtained from neonatal and adult hamsters inoculated s.c. with polyoma virus or polyoma tumor. The immunoglobulins containing tumor (T) and virus (V) antibody were detected in indirect fluorescent microscopy with fluorescein-labeled antisera specific for hamster 7S γ_1 -, 7S γ_2 -, γ A- and γ M-globulins. V antibody was seen in sera seven days after polyoma injection of neonates and was located in the 7S γ_2 -globulin only. T antibody was not seen until day 21 in neonates and was found in the 7S γ_1 - and 7S γ_2 -globulins. The IgM and IgA globulins contained no detectable antibody activity. 7S γ_1 anti-T activity was found both after virus inoculation of neonates and after tumor injection of adults. γ A antibody was never seen in hamster sera, but 7S γ_2 activity was always present. In young adult hamsters both V and T antibodies were detectable by seven days after virus inoculation. The T antibody in the 7S γ_1 -globulin may have enhanced tumor growth.

- 5261 POLYOMA PSEUDOVIRIONS. I. SEQUENCE OF EVENTS IN PRIMARY MOUSE EMBRYO CELLS LEADING TO PSEDOVIRUS PRODUCTION. (E.) Yelton, D. B. (U. Maryland Sch. Med., Baltimore) and H. V. Aposhian. *J Virol* 10(3):340-346, 1972.

Confluent monolayers of primary mouse embryo cells were infected with polyoma virus (0.1 plaque-forming U (PFU)/cell). At various times after infection, samples were taken and the temporal relationship of various intracellular events was determined. Synthesis of polyoma virus DNA began 18 hr postinfection. Formation of polyoma virus capsid protein began at 30 hr, as measured by an increase of empty capsids. Plaque-forming virus particles and pseudovirions appeared at 42 hr; by 96 hr, the synthesis of both was complete. Host cell DNA formation (16S DNA in alkaline gradients and 14S in neutral gradients) appeared 36 hr postinfection (16S DNA) or 72 hr postinfection (14S DNA). The amount of host cell 14S DNA produced was seven times greater than the amount of viral DNA produced. The relative pool sizes of polyoma DNA and 14S DNA at the time of virus assembly may dictate the amounts of polyoma virus and pseudovirus produced.

- 5262 REVERSE TRANSCRIPTASE-CONTAINING PARTICLES INDUCED IN ROUS SARCOMA VIRUS-TRANSFORMED RAT CELLS BY ARGININE DEPRIVATION. (E.) Kotler, M.

(Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel), E. Weinberg, O. Haspel and Y. Becker. *J Virol* 10(3):439-446, 1972.

Incubation of Rous sarcoma virus-transformed B77 rat embryo cells R(B77) for five days in medium deficient in arginine and containing ^3H -uridine resulted in the release of ^3H -labeled particles into the culture medium. Such particles, which banded at 1.16 g/ml in sucrose density gradients, did not appear in the medium of R(B77) cells incubated in medium containing arginine or in the medium of uninfected primary rat cells incubated either in arginine-deficient or complete medium. Electron microscopic observation showed that these particles resembled C-type particles. The particles released from the arginine-deficient R(B77) cells contained 35S RNA and reverse transcriptase activity. DNA synthesized by the reverse transcriptase in these particles hybridized with purified RSV RNA. The cytoplasm of both arginine-deprived and undeprived R(B77) and untransformed rat cells contained virus particles which banded in sucrose gradients at 1.14 g/cm and contained a reverse transcriptase. The DNA synthesized by this enzyme did not hybridize with purified RSV RNA.

- 5263 PATTERN OF PROTEIN SYNTHESIS IN MONKEY CELLS INFECTED BY SIMIAN VIRUS 40. (E.) Anderson, C. W. (Cold Spring Harbor Lab., N.Y.) and R. Y. Gesteland. *J Virol* 9(5):758-765, 1972.

Monolayer cultures of CV-1, BSC-1 or MA-134 monkey cells were infected with SV40 labeled with ^{35}S -methionine. To examine protein synthesis patterns in infected cells, total cell extracts were made by SDS and dithiothreitol disruption and analyzed by SDS-polyacrylamide gel electrophoresis. Between 15-18 hr postinfection, four virus-induced protein bands appeared. These proteins had molecular wts of 15,000-40,000 daltons, and were correlated with viral capsid proteins in three cases. The four bands appeared only after onset of SV40 DNA synthesis; they failed to appear in SV40-infected cultures treated with cytosine arabinoside and 5-fluorodeoxyuridine, inhibitors of SV40 DNA synthesis. The fourth protein band, which did not correspond to any viral capsid protein, did not appear in SV40-infected MA-134 cultures.

- 5264 C-TYPE VIRUS ASSOCIATED WITH GIBBON LYMPHOSARCOMA. (E.) Kawakami, T. G. (Sch. Vet. Med. U. California, Davis), S. D. Huff, P. M. Buckley, D. L. Dungworth and S. P. Snyder. *Nature (New Biol)* 58(235):170-171, 1972.

C-type virus particles were identified by electron microscopy in sections from lymph nodes, liver, spleen and bone marrow of a gibbon with disseminated lymphosarcoma. Similar extracellular C-type virions were also identified in preparations made from cultures of the tumor cells. The virions were approximately 100 nm in diameter, had an electron-dense nucleoid measuring approximately

75 nm, and banded at a density of 1.16 g/ml in sucrose gradients. Normal bovine, human and simian cells in culture were susceptible to infection and produced virions identical in morphology to those replicating from gibbon cell cultures. The virus induced neither morphological transformation of cell cultures nor cytopathic effect. The agent was identified as an RNA virus from its ability to incorporate ^3H -uridine. Purified virus possessed DNA polymerase activity. Preliminary serological evaluation of the virus antigen by immunodiffusion with sera against known feline, murine, rat and hamster oncogenic viruses showed that the agent lacked the species-specific antigen common to the known viruses. It did, however, possess an interspecific antigen common to known mammalian oncogenic viruses.

- 5265 "SPONTANEOUS" NEOPLASTIC TRANSFORMATION *IN VITRO*: INFLUENCE OF ENDOGENOUS MURINE LEUKEMIA VIRUS AND SERUM FRACTIONS. (E.) Sanford, K. K. (Natl. Cancer Inst., Bethesda, Md.), S. L. Handleman, J. W. Hartley, J. L. Jackson and R. R. Gantt. *J Nat Cancer Inst* 49(4):1177-1189, 1972.

Cell lines from three pools of normal C3Hf mouse-embryo cells were examined, during long-term culture, for both "spontaneous" neoplastic transformation and presence of murine leukemia virus group-specific antigens. Tests for neoplastic transformation were made by implantation of cells into syngeneic hosts and examination for sarcomas at the injection site. Cells were also examined cytologically for evidence of neoplastic transformation. No correlation between presence of antigen and neoplastic transformation could be established among the 48 cell lines studied. Tumors were produced by cells either positive or negative for group-specific antigens. Also, cells that did not undergo neoplastic transformation were either antigen positive or negative. These results do not confirm the hypothesis of a viral etiology for spontaneous neoplastic transformation of mouse cells *in vitro*. Differences in susceptibility to neoplastic transformation between embryo cell pools were observed. In addition, the effects of various fractions of fetal bovine serum on neoplastic transformation were explored. Under the conditions of these experiments, no one fraction consistently delayed or accelerated neoplastic transformation as compared with whole unfractionated serum.

- 5266 ONCOGENIC ACTIVITY OF POLYOMAVIRUS IN THE RAT. (Ger.) Desselberger, U. (Med. U., Hanover, West Germany), A. Georgii, H. Zobl and H. Ostertag. *Zentralbl Bakteriol (Orig)* 219(1):28-38, 1972.

The effect of thymectomy on oncogenesis and on the formation of hemagglutination inhibitor (HAI) antibodies against polyoma virus (S.E. strain) suspensions was investigated with the aid of the ultracentrifuge. Nursing Wistar rats were infected 24 hr after birth by an injection (s.c.) of 0.3 ml of

dialyzed supernatant fraction sediment or starting material of the virus. The animals were sacrificed 30 days later and their kidneys examined for tumors by macroscopic and histological observations. The supernatant fractions of the virus suspensions showed a marked increase in both oncogenicity and antigenicity compared with the other forms of the injected virus. The reason for this was a relative decrease in the infectivity titer of the supernatant fraction in the presence of inhibitors, which mask a portion of the infectious virus. When dialyzed material was used, the sediment suspension contained much higher quantities of virus than the starting material, as calculated on the basis of the infection titer before dialysis. With ultracentrifugation, about 90% of the virus particles in suspension settled into the sediment. Antibody response and tumor rate correlated with the dose of infective virus inoculated per animal (except for the supernatant fraction), which suggests that the *in vivo* inhibitors do not act in the same manner as the *in vitro*. In most groups infected with the same viral dose, there were no differences in antibody response between animals with and without tumors. Thymectomy led to a decreased antibody formation. Thymectomized animals receiving the starting material as a virus suspension showed an increase in tumor formation compared with controls.

- 267 HORMONAL MODIFICATION OF ADENOVIRUS TRANSFORMATION OF HAMSTER CELLS *IN VITRO*. (E.)
 Milo, G. E. Jr. (Dept. Vet. Microbiol. Parisitol., Ohio St. U., Columbus), J. P. Schaller and D. S. John. *Cancer Res* 32(11):2338-2347, 1972.

Primary hamster embryo cells were grown *in vitro* with Dulbecco's minimal essential medium supplemented with 10% dialyzed, virus-screened fetal calf serum and adjusted to 0.1 mM Ca^{++} . Cultures were segregated according to sex. Human adenovirus type 12 (Ad-12) induced foci of morphologically transformed cells in both sexes 10-12 days postinfection. The number of foci in replicate cultures did not vary statistically. Consistently more foci developed in female cultures than in similarly infected male cultures. Transformation was more efficient in pooled cultures of the same sex than in cultures grown from a single embryo. Significant enhancement ($p < 0.01$) of transformation occurred in female cultures treated with cortisone acetate, 5 µg/ml, and in male cells treated with dexamethasone, 0.1 µg/ml. Marked inhibition ($p = 0.001$) of Ad-12 transformation occurred in female and male cells treated with estrovarin, 0.1 µg/ml, and of male cells treated with aldosterone, 10 µg/ml, or progesterone, 10 µg/ml. Estrone and testosterone inhibited transformation of male cells slightly less markedly ($p < 0.01$) and had no effect on female cells. The mechanisms of enhancement and of inhibition are not clear. Cortisone acetate did not prevent cytotoxic effects (cell killing) in female cells by Ad-12. It seemed unlikely that cortisone acetate acted directly on the virus. The efficiency of transformation of hamster cells by Ad-12 is influenced by interrelationships between calcium concentration in the media, glucocorticoid activity of the steroid, and cell sex.

- 5268 VIRUS-LIKE PARTICLES IN GUINEA PIG OOGONIA AND OOCYTES. (E.) Andersen, H. K.
 (Inst. Med. Microbiol., U. Aarhus, Denmark) and Th. Jeppesen. *J Nat Cancer Inst* 49(5):1403-1410, 1972.

Virus-like particles in oogonia and oocytes of fetal, neonatal, and adult albino guinea pigs of the short-haired British type were observed with the electron microscope. The particles were identical to the guinea-pig leukemia virus in morphology and intracisternal cytoplasmic location. Three types of spherical particles 800-900 Å, in different stages of maturity and one crescent-shaped type, presumably in the stage of formation by budding from cytoplasmic vesicles, were noted. The particles were seen only intracisternally in membrane-limited cytoplasmic areas (probably of the endoplasmic reticulum) or between the two nuclear membranes and were never found in germinal cell nuclei or in any other ovarian cell type. Attempts to cultivate the virus on tissue culture cells of fetal guinea pigs, rabbit kidney cells, and explant cell cultures have not been successful. Another virus, morphologically resembling herpesvirus, was isolated from two adult animals by these attempts.

- 5269 FATE OF INFECTING SIMIAN VIRUS 40-DEOXYRIBONUCLEIC ACID IN NONPERMISSIVE CELLS: INTEGRATION INTO HOST DEOXYRIBONUCLEIC ACID. (E.)
 Collins, C. J. (German Cancer Res. Ctr., Heidelberg, West Germany) and G. Sauer. *J Virol* 10(3):425-432, 1972.

A kinetic analysis of conformational changes of simian virus 40 (SV40) donor DNA on infection of nonpermissive 3T3 cells is reported. Nonpermissive 3T3 cells were infected with purified superhelical SV40 deoxyribonucleic acid I (DNA I). One hour after infection, approximately 60% of the intracellular SV40 DNA was converted to relaxed forms. One day after infection, all intracellular SV40 DNA was present as slow-sedimenting material, and no SV40 DNA I was detectable. At 2 days after infection there appeared viral DNA sequences cosedimenting with cellular DNA during alkaline velocity centrifugation. Furthermore, by both alkaline equilibrium gradient centrifugation and by DNA-ribonucleic acid hybridization analysis, covalent linkage of viral DNA sequences to cellular DNA was demonstrated. Integration of SV40 DNA into cellular DNA did not appear to require DNA synthesis, although DNA synthesis followed by mitotic division of the cells enhanced the amount of viral DNA integrated. Based on data obtained by two different methods, it was calculated that 1,100 to 1,200 SV40 DNA equivalents must be integrated per cell by 48 hr after infection.

- 5270 SOME RESULTS OF STUDIES ON SKIN HETEROGENIZATION PRODUCED BY A LATENT VIRUS FROM C57B1/6J MICE. (Rus.) Liozner, A. L. (Sci. Res. Inst. Vir. Prep. Moscow, USSR), G. Ya. Svet-Moldavskiy, D. M. Mkheidze, P. P. Sokolov, T. A. Litovchenko and A. F. Bykovskiy. *Vestn Akad Nauk SSSR* 26(7):74-81, 1971.

Skin heterogenization tests were done on mice of lines C57Bl/6J, BALB/c, CBA, C3H, C3HA, and T6T6. 7,12-dimethylbenzanthracene (0.5 mg) was injected i.m. in mice in order to induce tumors in three to five months. The tumors were implanted in syngeneic mice subcutaneously. The transplants were examined in five to six days after transplantation, when the primary adaptation or rejection of the transplants was seen. The rejection response of the skin transplanted from carriers of K-237 sarcomas to syngeneic recipients of C57Bl/6J line (320 mice) was identical to the rejection response of the allogeneic transplants. The heterogenization response appeared in 8-13 days. Histologically, there was a resemblance in the rejection response of syngeneic and allogeneic transplants, with dilation of the blood vessels, cellular infiltration, activation of the connective tissue. The heterogenizing activity of the virus-containing tumor extract was neutralized by hyperimmune sera of C57Bl/6J mice. Virus particles of approximately 180 Å size were seen in deposits of the centrifuged extract examined under the electron microscope. None of 87 primary sarcomas of C57Bl/6J mice, induced by 7,12-dimethylbenzanthracene, caused heterogenization of the skin in these mice. But the tumors of the same type and cell-free extracts of these tumors acquired the heterogenizing effect after two to five passages on syngeneic mice. These results indicate that the virus causing the heterogenization phenomenon is a virus latent in C57Bl/6J mice and activated in tumors. Sarcomas induced in other lines of mice did not cause heterogenization. Heterogenization developed in C57Bl/6J mice as the number of passages increased up to 22. After the 22nd passage, the heterogenizing effect decreased.

- 5271 VIRUS PRODUCTION INDUCED BY VARIOUS CHEMICAL CARCINOGENS IN A VIROGENIC HAMSTER CELL LINE TRANSFORMED BY ROUS SARCOMA VIRUS. (E.) Altanerova, V. (Cancer Res. Inst., Bratislava, Czechoslovakia). *J Nat Cancer Inst* 49(5):1375-1380, 1972.

Virus was produced by two chemical carcinogens and four mutagens in a hamster cell line transformed by the Schmidt-Ruppin strain of Rous sarcoma virus. This cell line does not produce infectious virus or any C-type particles. The chemical carcinogens were 3-methylcholanthrene and benzo[a]pyrene. The mutagens were 4-nitroquinoline-1-oxide, urethan, 5-azacytidine, and phytohemagglutinin. The transformed hamster cell line was treated with various concentrations of these agents administered at different frequencies. In subsequent passages of treated cells, virus production was investigated by the inoculation of cell-free medium into 1-day-old chickens. Virus was first seen in the tenth passage of the treated cells. Virus was induced in all treated cell lines except those treated with urethan and phytohemagglutinin. Tumors induced in chickens by virus obtained from treated cells were sarcomas, which produced fully infectious virus for chickens.

- 5272 ALKALINE PHOSPHATASE ACTIVITY IN SPONTANEOUS AND INDUCED LEUKEMIAS IN SJL/J MICE. (E.)

Haran-Ghera, N. (Weizmann Inst. Sci., Rehovoth, Israel), R. Hauch-Granoth and H. Neumann. *Cancer Res* 32(11):2475-2480, 1972.

Alkaline phosphatase levels were determined in the thymus, spleen, and liver and in the mesenteric and peripheral lymph nodes of SJL/J mice with spontaneous or induced types of leukemia. Lymphatic leukemia, whether spontaneous or induced either by a leukemogenic virus or by 7,12-dimethylbenz(a)anthracene, caused a marked elevation in alkaline phosphatase activity in the tissues tested. This enzymatic activity increase is not thymus dependent but, rather, is a characteristic feature of murine lymphatic leukemia development, since it also occurred in thymectomized mice treated with 7,12-dimethylbenz(a)anthracene. In SJL/J mice that developed spontaneous reticulum cell neoplasms or myeloid leukemia (induced by irradiation), the levels of alkaline phosphatase activity were similar to normal levels.

- 5273 COURSE OF INFECTION IN TISSUES OF SUSCEPTIBLE CHICKENS AFTER EXPOSURE TO STRAINS OF MAREK'S DISEASE VIRUS AND TURKEY HERPESVIRUS. (E.)

Phillips, P. A. (Poultry Res. Station, Houghton, Huntingdon, England) and P. M. Briggs. *J Nat Cancer Inst* 49(5):1367-1373, 1972.

A study was made of infection in tissues from highly susceptible chickens exposed by inoculation or contact with virulent (HPRS-16) and avirulent (HPRS-27) and attenuated (HPRS-16) strains of Marek's disease virus (MDV) and turkey herpesvirus (HVT). Virus of all strains was first detected in lung and lymphoid tissues, and one strain was found one day after inoculation. All viruses persisted in infected birds for the duration of the experiments (about 60 days) and produced high levels of cell-associated infectivity in the lung, spleen, and liver. The level of infectious virus in most tissues was significantly higher in birds infected with the HPRS-16 strain of MDV, which cause acute Marek's disease, than in birds infected with HVT, HPRS-27, and attenuated HPRS-16. Direct comparisons showed no significant difference in levels of cell-associated infectivity in most tissues of chickens infected with HVT, HPRS-27, and attenuated HPRS-16; other comparisons suggested that infectivity was lowest in chickens infected with attenuated HPRS-16. These findings correlated positively with the relative pathogenicity of the viruses in susceptible chickens. Attenuated acute MDV and HVT were not transmitted by contact exposure, but the apathogenic strain of MDV was transferred to susceptible birds by this means.

- 5274 NUCLEIC ACID METABOLISM IN CELLS DURING THE EARLY STAGES OF INTERACTION WITH ONCOGENIC VIRUSES. (Uk.) Nadhorna, N. Y. (Sci. Res. Inst. Epid., Microbiol., Parasit., Kiev, USSR), M. R.

Mednyk, L. D. Shkraba and A. M. Shcherbyns'ka.
Mikrobiol Zh 34(1):41-42, 1972.

Mouse and chicken embryo fibroblast (MEF and CEF) cultures were inoculated with Polyoma and Rous sarcoma viruses, and the dynamics of nucleic acid levels and mitotic activity were studied during the first 24 hr after viral infection. Rous sarcoma virus caused an increase in DNA levels and H^3 -thymidine-labeled cells in the CEF cultures between 2-11 hr postinoculation. A drop in these indexes on the 12th hr and a subsequent gradual increase through the 22nd hr of the experiment were observed. Mitotic activity of the infected cultures increased with respect to the control cultures on the 5th through the 18th hr of the experiment; its decrease toward the end of the 24 hr experiment appeared to be associated with increased RNA levels. Increased DNA levels, cellular label incorporation, and labeled cell amounts were observed in the MEF cultures upon inoculation with Polyoma virus; label indexes of the experimental cultures reached an average 68% as compared with 54% found in the related controls. All these parameters decreased between the 5th and 22nd hr of the experiment, then increased over control values at the end of the 24 hr period. The decrease of mitotic activity observed during the major part of the experiment was attributed to an inhibition of DNA synthesis. The different trends in nucleic acid metabolism and mitotic activity caused by the two viruses were interpreted as due to the different nature of the Rous oncorna and Polyoma DNA viruses.

5275 STRUCTURAL ROLES OF POLYOMA VIRUS PROTEINS.
(E.) Friedmann, T. (U. California San Diego Sch. Med., La Jolla) and D. David. *J Virol* 10(4):776-782, 1972.

Polyoma viruses were subjected to alkaline disruption and the protein composition of disrupted viruses was examined by electrophoresis in SDS-12.5% polyacrylamide gels. The released virion DNA was seen as a 25S peak associated with 4-6% of recovered virion protein (superhelical closed circular double-stranded DNA) and as a 17S peak of protein-free DNA (nicked viral or linear DNA). Most viral protein disruption was in the form of capsomeres, sedimenting mainly at 10S and 7S. Both these protein peaks contained proteins P_2 , P_3 and P_4 in molar ratios of 5:1:1 or 6:1:1. The 25S DNA-protein complex contained only a small amount of the major capsid protein in P_2 . Material found between 1-3S was rich in P_5 and contained some P_2 , P_3 and P_4 . Reassembled DNA-free shell-like particles contained P_1 , P_2 , P_4 and P_7 in amounts similar to those seen in native virions. Reassembled particles had reduced amounts of P_3 , virtually no P_5 and probably no P_6 .

5276 THE RADIO-LEUCOSIS VIRUS OF THE C57B1 MOUSE. (Fr.) Legrand, E. (Bergonie Fdn., Bordeaux, France) and P. B. Mistry. *Bord Med* 7:763-769, 1972.

The mechanisms for leukemogenesis in C57 B1 mice are reviewed. Frequency of spontaneous leukemias is less than 7%, but following X-ray radiation under controlled conditions, the percentage of leukemias is considerably increased (80-90%). Unless the whole body is exposed to the radiation, the leukemia may be inhibited. Inhibition also occurs following injections of cellular suspensions prepared from bone marrow, and from fetal liver or spleen. Experiments are described showing that a thymus grafted onto a thymectomized and irradiated animal becomes leukemic. However, it was demonstrated that a leukemogenic agent, of a viral type, existing in irradiated sarcoma tissues may be transmitted to neonates to induce lymphoid tumors. Irradiation apparently promotes an accumulation of target cells maximally susceptible to becoming leukemic cells. Thus, a minimal superinfection may contribute to the development of lymphosarcomas in animals who would otherwise not succumb to carcinogenesis.

5277 SUSCEPTIBILITY OF INBRED FISCHER RATS TO BRAIN TUMOR INDUCTION BY ROUS SARCOMA VIRUS. (E.) Wilfong, R. F. (Duke U. Med. Ctr., Durham, N.C.), D. D. Bigner and W. Wechsler. *Naturwissenschaften* 59(8):371-372, 1972.

Twenty-five neonatal, inbred rats were injected intracerebrally with 0.01 or 0.02 ml of a preparation of Rous sarcoma virus, Schmidt-Ruppin strain. Solitary or multiple tumor growth occurred in 24 rats three months after inoculation. A total of 57 microscopic or large macroscopic tumors were present. They were located in the meninges, the hemispheres, the basal ganglia, the cerebellum, and the ventricle. No extraneural tumors or metastases were found. The brain tumors fell into three main categories: gliomas (34); mixed tumors (gliosarcomas) (5); and sarcomas (18). The majority of tumors were of neuroectodermal nature and originated from the subependymal region and the white matter.

5278 CLEAVAGE OF SIMIAN VIRUS 40 DNA AT A UNIQUE SITE BY A BACTERIAL RESTRICTION ENZYME. (E.) Morrow, J. F. (Stanford U. Med. Ctr., Calif.) and P. Berg. *Proc Natl Acad Sci USA* 69(11):3365-3369, 1972.

5279 SPECIFICITY OF THE BREAK PRODUCED BY RESTRICTING ENDONUCLEASE R_1 IN SIMIAN VIRUS 40 DNA, AS REVEALED BY PARTIAL DENATURATION MAPPING (E.) Mulder, C. (Cold Spring Harbor Lab. Quantitative Biol., N.Y.) and H. Delius. *Proc Natl Acad Sci USA* 69(11):3215-3219, 1972.

5280 MORPHOGENESIS AND STRUCTURE OF ONCORNA VIRUSES: ELECTRONMICROSCOPIC STUDIES ON C-TYPE VIRUS PARTICLES. (Ger.) Gelderblom, H. (Max Planck Inst. Vir. Res. Tübingen, Germany), H. Bauer, D. P. Bolognesi and H. Frank. *Zbl Bakt (Orig)* 220:79-90, 1972.

- 5290 QUANTITATIVE ANALYSIS OF IgG, IgA AND IgM IMMUNOGLOBULINS IN LYMPHATIC LEUKEMIA AND LYMPHOSARCOMA. (E.) Lawkowicz, W. (Inst. Hematol., Warsaw, Poland), M. Kraj and S. Ciesluk. *Arch Immunol Therap Exp (Warsz)* 20:227-234, 1972.

Electrophoretic γ -fractions, and levels of IgG, IgA and IgM immunoglobulins were determined in blood sera from 42 patients with chronic lymphatic leukemia, lymphosarcoma, chronic lymphatic leukemia developing into lymphosarcoma, reticulosarcoma, reticulosis or lymphadenopathy. In lymphatic leukemia, the γ -fraction and mean immunoglobulin values were lower than in healthy persons. In lymphosarcoma and reticulosis, γ -fraction and immunoglobulin values were normal. M proteins, which in lymphoproliferative states may be a product of cells involved in the proliferative process, were seen in to cases of lymphosarcoma; one case showed M-IgGK and the other showed M-IgM. IgM protein was also seen in one leukemia patient. IgG and IgA were reduced, and IgM was slightly elevated, in patients with leukemia evolving into lymphosarcoma; in these patients, γ -fraction values were normal. In reticulosarcoma and lymphadenopathy, the results were variable.

- 5291 DETERMINATION OF β -NAPHTHYLAMINE AS A HAPTENE IN CANINE TISSUES IN EARLY STAGES OF CARCINOGENESIS. (Rus.) Korosteleva, T. A. (N. N. Petrov Res. Inst. Oncol., Min. Health USSR, Leningrad) and A. P. Skachkov. *Vopr Onkol* 18(7):69-73, 1972.

Formation of carcinogen-protein antigen complexes under the effect of β -naphthylamine was studied in the urinary bladder of dogs with cancer. The dogs received food containing 50 mg/kg β -naphthylamine. Blood from these dogs was collected 4, 15, and 30 days from the beginning of such diet for immunological examinations. Extracts of the liver, kidneys, spleen, urinary bladder and lungs were also used for detection of the carcinogen-protein antigens. β -naphthylamine-haptene was detected using rabbit immune sera to synthetic heterologous β -naphthylamine-azoproteins and agar gel filtration. β -naphthylamine-haptene complex was found in the sera of dogs which had received β -naphthylamine for 15-30 days. The number of animals with such complex in their sera increased in accordance with the number of days of administration of β -naphthylamine. The antigen complex was also found in the protein of kidney extracts of dogs which had received β -naphthylamine for 15-30 days, but not in other tissues.

- 5292 IMMUNOLOGIC REACTIVITY OF THE CAT: IMMUNOSUPPRESSION IN EXPERIMENTAL FELINE LEUKEMIA. (E.) Perryman, L. E. (Coll. Vet. Med., Ohio St. U., Columbus), E. A. Hoover and D. S. Yohn. *J Nat Cancer Inst* 49(5):1357-1365, 1972.

Cellular and humoral immune capabilities were evaluated in 18 cats inoculated at birth with feline leukemia virus and in 16 age-matched control cats.

The assays were performed at 2-week intervals between 5 and 19 weeks of age. All control cats rejected cutaneous allografts at 13.1 ± 1.4 days. Sixteen of eighteen FeLV-infected cats (89%) had significantly ($P < 0.01$) longer allograft retention times (≥ 18 days). These differences were first noted in 5-week-old cats. Humoral antibody responsiveness (measured by hemagglutination titers to sheep red blood cells) was not significantly altered during leukemogenesis. Marked thymic atrophy appeared in the infected cats as early as 5 weeks of age, and persisted into the neoplastic period (19 weeks of age). These results indicate that significant depression of cell-mediated immunity occurs in the preneoplastic phase of experimental feline lymphosarcoma, and that thymic atrophy is a preleukemic lesion.

- 5293 IMMUNE STATUS OF AUTOCHTHONOUS AND ADOPTIVELY PROTECTED MICE TOWARD SPONTANEOUS AND CHEMICALLY INDUCED TUMORS. (E.) Basombrio, M. A. (Inst. Cancer Res., Philadelphia, Pa.) and R. T. Prehn. *Cancer Res* 32(11):2545-2550, 1972.

The immune reactivity of mice toward their own primary tumors was evaluated immediately after surgical excision of the tumor, with or without procedures to establish adoptive tumor immunity. Methylcholanthrene (MCA)-induced sarcomas and "spontaneous" mammary carcinomas of C3H/He mice were used. Autografts of either of these tumors grew better than isografts into normal mice. This conditioned status of primary hosts bearing MCA tumors could not be transferred to syngeneic recipients by means of lymphoid cells or serum. On the other hand, attempts to transfer specific immunity from actively immunized mice to syngeneic recipients were successful. When mice bearing primary or transplanted tumors were lethally irradiated and repopulated with lymphoid cells from normal or tumor-immunized donors, tumor growth was markedly inhibited. This treatment was effective for MCA-induced sarcomas in both inbred and random-bred mice, but not for spontaneous mammary carcinomas. Procedures involving repopulation of tumor-bearing mice with lymphoid cells from normal or immunized mice seem to correct a decreased level of reactivity of the animals toward their own tumors.

- 5294 THE IMMUNODEPRESSIVE AND CARCINOGENIC ACTIVITY OF FOUR N-NITROSO-COMPOUNDS IN MALE SPRAGUE DAWLEY RATS. (Ger.) Scherf, H. R. (Inst. Exp. Toxicol. Chemother., Heidelberg, Germany). *Z Krebsforsch* 77(3):189-193, 1972.

The carcinogenic dimethylnitrosamine, ethyl-n-butyl-nitrosamine, N-nitrosomorpholine, and methylnitrosourea were administered to male Sprague-Dawley rats in four equitoxic doses each, once weekly, for 12, 18, and 24 wk. Following completion of each treatment period, the compounds were tested for their immuno-depressive properties by the Jerne plaque test. The four substances affected the immune competent system of the rats very differently.

A definite inhibition of the immune reaction was observed in rats treated with dimethylnitrosamine at the three higher dose levels, whereas only the highest dose level of N-nitrosomorpholine or ethyl-n-butyl nitrosamine inhibited an immune reaction. The immunodepressive effect of methylnitrosourea was already evident after 12 weeks of its administration but did not increase through further administration. No correlation could be found between the carcinogenic and immunodepressive properties of the compounds tested.

- 5295 STUDIES ON THE IMMUNOLOGY AND PROTEIN STRUCTURE OF CARCINOMA OF THE UTERINE CERVIX. (Ger.) Loskant, G. (Women's Clin. U. Homburg, West Germany). *Ann Univ Saraviensis Med* 18(4):207-303, 1971.

An attempt to interpret human carcinoma of the uterine cervix as an immune disease is made. In this connection tissue proteins as antigens are particularly relevant. Electrophoretic studies of the patients revealed a decrease in albumin peaks and an increase in globulin fractions, with a highly significant increase in total protein. In 12 carcinoma patients, there was an increase in serum protein acid alpha₁, -glycoproteins, ceruloplasmin, haptoglobin, gamma-alpha-globulin, and gamma-alpha-G-globulin, whereas the albumin, alpha₂-macroglobulin, transferrin and the gamma-M-globulin were decreased. The effect of beta irradiation on the serum was not clear-cut. Electrophoretic analyses by means of the ultracentrifuge confirmed the protein disorders in all the carcinomatous cells. It is possible to demonstrate the protein deficit in the carcinomatous organs by the use of specific plasma protein antisera. Antigen loss occurs particularly in the cell subfractions. The serum protein changes do not reflect the events in carcinoma tissue. (656 references).

- 5296 IMMUNOFLUORESCENT CHARACTERISTICS OF EXPERIMENTAL BLASTOGENESIS OF THE THYROID. (Rus.) Okulov, V. B. (N. N. Petrov Res. Inst. Oncol., Leningrad, USSR). *Vopr Onkol* 18(8):54-61, 1972.

Various stages of experimental oncogenesis in the thyroid gland were studied in white rats by an immunofluorescent method. A total of 30 hybrid white rats (2-3 months old and weighing 100-120 g) received 20 mg 6-methylthiouracil in 0.2 ml water through a gastric catheter five times a week. Fifteen white rats served as controls. Six to 25 months from the beginning of the experiment, the animals were killed with chloroform vapors and their thyroid glands were removed and prepared for immunofluorescent and microscopic analyses. A total of 28 epithelial tumors of varied structure and five local follicular proliferates were found in 22 animals receiving 6-methylthiouracil. Nine of the tumors were malignant. The microsomal antigen was determined utilizing chick gammaglobulin antisera labeled with a fluorescent color. The content of the microsomal antigen was significantly decreased in the

five local proliferates and even more decreased in the nine malignant tumors. In four vascular infiltrating tumors, the microsomal antigen was barely detectable. Thus, the different microsomal antigen levels reflect various stages of tumor development.

- 5297 IMMUNOLOGY OF LIVER CANCER IN JAPAN AND SOUTH EAST ASIA WITH SPECIAL REFERENCES TO AUSTRALIA ANTIGEN. (E.) Nishioka, K. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan). *Asian Med J* 15(2):47-49, 1972.

The occurrence of Australia antigen (Au-Ag) was observed in 467 hepatoma patients in Japan, Taiwan, Manila and Singapore. Between 33.6 and 70.0% of the hepatoma patients possessed Au-Ag, as determined by immune adherence hemagglutination; the percentages of Au-Ag positivity among subjects without hepatoma did not exceed 13.5%. No anti-Au antibody could be demonstrated in most Au-Ag-positive hepatoma patients. Seventy-four of 196 hepatoma patients who were α -fetoprotein-positive were Au-Ag-positive, while only seven of 40 α -fetoprotein-negative hepatoma patients were Au-Ag-positive.

- 5298 ALTERATIONS IN PLASMA RECOGNITION FACTOR ACTIVITY IN EXPERIMENTAL LEUKEMIA. (E.) Di Luzio, N. R. (Tulane U. Sch. Med., New Orleans, La.), E. Miller, R. McNamee and J. C. Pisano. *J Reticuloendothel Soc* 11:186-197, 1972.

Liver slices from normal rats were incubated with normal rat sera and heparin and exposed to particles of a gelatinized RE test lipid emulsion labeled with ¹³¹I-triolein. The expression of humoral recognition factor (HRF) by liver Kupffer cells was measured by observing phagocytosis of ¹³¹I-triolein labeled lipid emulsion by Kupffer cells. The incubation of liver slices with normal rat plasma resulted in a 17-fold increase in phagocytosis as compared to the degree of phagocytosis in mixtures of rat liver slices and lipid emulsion incubated with phosphate buffer. Serum from rats injected with normal leukocytes did not alter the expression of HRF by Kupffer cells. However, when liver slices and lipid emulsion were mixed with sera from rats given transplants of Shay chloroleukemia cells, HRF expression was depressed by 80%. The i.v. administration of leukemic cells to rat serum donors also depressed HRF expression; however, in the i.v. system, HRF was restored to normal values by 4 hr. The role of altered HRF activity in neoplasia is discussed.

- 5299 MALIGNANT CELLULAR TRANSFORMATION AND KARYOLOGIC MODIFICATIONS: THE CONTRIBUTION OF INTRASPECIFIC SOMATIC HYBRIDIZATION IN CHINESE HAMSTERS. (Fr.) Berebbi, M. (Regional Anti-Cancer Ctr., Marseilles, France) and G. Meyer. *Int J Cancer* 10(2):418-435, 1972.

Different characteristics of transformation were studied on subclones isolated from a hybrid cell line (HyC) obtained by fusion of two Chinese hamster sublines, similar in origin but differing in properties such as transplantability. Different sublines were derived by cloning in soft agar. Transplantability, plating efficiency in soft agar, agglutinability by Concanavalin A were studied in parallel with karyotypic evolution to establish a possible correlation. DC-3F, one of the parent strain, spontaneously transformed *in vitro*, produced tumors when inoculated in the cheek pouch of cortisone-treated Syrian hamsters, grew easily in soft agar and was highly agglutinable by Concanavalin A. In contrast, the second parent strain, DC-3F/ADX/Aza, had lost its tumor-producing ability; it did not grow in soft agar and was poorly agglutinated by Concanavalin A. The HyC population had intermediate cloning and agglutinability characteristics. Clones isolated from the HyC line showed differences in tumorigenicity that appeared to be correlated with modifications of their surface properties. A statistical chromosomal analysis was performed using the appearance of a distinctive abnormal subtelocentric chromosome (M2) as a marker for the HyC line. The arithmetical mean of the M2 marker (0.85) varied in the HyC subcultures and also in the clones studied. A relationship was observed between the marker and percentage of tumors, but comparative statistical analysis indicated that the M2 marker was not the unique chromosome responsible for malignancy. The marker is, however, involved in modifications of the cell surface.

5300 TRANSITORY CELL ANTIGENS OF RAT LIVER.
II. EFFECT OF SYNTHESIS INHIBITORS ON FETOSPECIFIC SERUM PROTEINS IN NORMAL YOUNG ANIMALS AND AFTER ACUTE HEPATIC INJURY. (Fr.) De Nèchoud, B. (Cancer Sci. Res. Inst., Villejuif, France) and J. Uriel. *Int J Cancer* 10:58-71, 1972.

Young Wistar rats were tested for the effect of protein synthesis inhibition on serum α -fetoprotein (FP) levels and on the *in vivo* synthesis of α -FP during acute liver injury. Actinomycin D and cyclohexamide were selected as the two inhibitors that intervene at different levels of expression of the cellular genome, blocking transcription and translation, resp. The inhibitors were administered i.p. in doses of 50-100 μ g/100 g body wt. Cyclohexamide decreased serum α -FP and lipoprotein-esterase in rats less than one month old but had no effect on α -FP or albumin. Actinomycin decreased α -FP but not α -FP in young animals. Until the age of two and a half months, a single i.p. injection of 1.25 or 2.5 mg of hepatotoxic N-dimethylnitrosamine induced the transitory secretion of significant quantities of α -FP. The *de novo* synthesis of α -FP and α -FP during liver injury was evidenced by incorporation of L-leucine- C^{14} and its inhibition by cyclohexamide. Reappearance of α -FP following dimethylnitrosamine injection was delayed by moderate doses of actinomycin D. The synthesis of α -FP in both the normal and liver-damaged rat in

the presence of actinomycin D indicates the presence of messenger RNA at time of administration of the inhibitor.

5301 THE INFLUENCE OF PARASITISM WITH *DIPETALONEMA VITAE* AND WITH *SCHISTOSOMA MANSONI* ON THE GROWTH OF EXPERIMENTAL TUMORS. (Fr.) Capron, A. (Fac. Med., Lille, France), P. Wattre, M. Capron and M.-N. Lefebvre. *C R Acad Sci [D] (Paris)* 275:719-722, 1972.

A study of the interaction between tumor cells and parasitic larvae is presented. The tumor cells were BHK 21 C 13, cultured *in vitro* and injected s.c. in a dose of 1×10^6 /animal (Syrian hamster) and 8629 T 1 C5⁽⁵⁾ from tumor nodules of the Fisher rat, administered at 5×10^6 /rat. The parasites were L III larvae of *Dipetalonema vitae* (D.v.) filaria; at 200/animal and the furcercous *Schistosoma mansoni* (S.m.) at 100/animal for inoculation in the hamster. In the rat, S.m. was inoculated at 800/animal. Parasitic infestation was carried out before, during, or following the administration of tumor cells, the controls receiving either the cells or the parasites. BHK 21 cells were administered to groups of five hamsters infected with parasites at different time intervals. In hamsters infected 75 days previously with D.v., there was an accelerated growth of tumors whose mean diameter in 42 days was twice that of the control; in animals infected with D.v. at the same time as injection of tumor cells, there was an inhibition of tumor growth. The other groups developed similarly to the controls. In hamsters given BHK 21 cells 30 days after infection with S.m., tumor growth was accelerated, tumors attaining at 50 days a weight six times that of the controls. With S.m. there was also an inhibition of tumor growth upon simultaneous administration of tumor cells and parasites, and no difference from controls was seen at other time intervals. The 8629 T 1 C5 cells were injected in groups of five rats 20 days before, 20 days after, or at time of parasite infection. With simultaneous administration, tumors developed which were similar to those in the controls; no tumors appeared in the other groups. The interaction between tumor cells and parasites is shown to depend on the sensitivity of the host to the specific parasite. A new approach to tumor development in countries where bilharziasis is endemic is indicated.

5302 IMMUNOCYTOLOGY OF CULTURED IgM-FORMING CELLS OF MOUSE I. REQUIREMENT OF PHAGOCYTIC CELL FACTOR FOR THE GROWTH OF IgM-FORMING TUMOR CELLS IN TISSUE CULTURE. (E.) Namba, Y. (Inst. Virus Res., Kyoto U., Japan) and M. Hanaoka. *J Immunol* 109(6):1193-1200, 1972.

Murine IgM-forming myeloma MOPC-104E cells induced in BALB/c mice were able to grow in tissue culture for only about one month when fed every three days with regular medium. Growth in culture was prolonged for as long as ten months when the cells were fed regularly with medium supplemented with a factor from

cultured mouse spleen cells or peritoneal macrophages. This factor was precipitated with ammonium sulfate. It was fairly heat labile, proteinaceous and had a molecular wt of about 5×10^4 as determined by Sephadex gel filtration. The factor was stable for two days at 37 C and for three months at -20 C. MOPC-104E cells grown in factor-deficient medium accumulated in the G₁ phase of the cell cycle, and transfer to factor-containing medium resulted in a synchronous wave of DNA synthesis and mitosis. The factor did not regulate IgM production by the tumor cells. Cyclic AMP (0.3 to 1.0 μ g/ml) could substitute for the factor, suggesting a possible role as second messenger in DNA synthesis of tumor cells. While sera of young adult A/Jax mice contained a small amount of the growth-promoting factor, activity was greatly increased by injection of Freund's complete adjuvant. L cells and mouse embryo cells did not produce the factor, and sera from rabbit, horse or cattle showed no detectable activity.

- 5303 THE IMMUNE RECOGNITION OF TA3 TUMORS, ITS FACILITATION BY ENDOTOXIN, AND ABROGATION BY ASCITES FLUID. (E.) Grohsman, J. (Temple U. Sch. Med., Philadelphia, Pa.) and A. Nowotny. *J Immunol* 109(5):1090-1095, 1972.

TA3-St and TA3-Ha mouse mammary tumors, maintained in A/J mice, were exposed to 10,000 R X-irradiation and injected i.p. into mice to immunize them against subsequent tumor challenge. A/J, A/St and C57BL/10Sn mice rejected TA3-St or TA3-Ha tumor challenges of from ten to 100 times the TD₅₀ for these tumors following repeated immunization with 10⁸ or 10⁷ irradiated tumor cells. TA3 tumor resistance was achieved in ICR mice by engrafting them with strain A mouse skin. Following rejection of the skin grafts, ICR mice were resistant to TA3-Ha challenge. Endotoxin, injected into C57BL/10Sn mice before TA3-Ha challenge, resulted in three of ten mice developing tumors; all of ten mice given TA3-Ha cells but not endotoxin developed tumors. A/St mice were protected against TA3-St cells when simultaneously injected with spleen cells from syngeneic TA3-St tumor-bearing mice. However, ascites fluid from spleen cell donors promoted TA3-Ha growth.

- 5304 CYTOTOXIC ANTIBODY IN NORMAL HUMAN SERUMS REACTIVE WITH TUMOR CELLS FROM ACUTE LYMPHOCYTIC LEUKEMIA. (E.) Bias, W. B. (Johns Hopkins U. Sch. Med., Baltimore, Md.), G. W. Santos, P. J. Burke, G. M. Mullins and R. L. Humphrey. *Science* 178(4058):304-306, 1972.

Complement-dependent cytotoxic sera specific for acute lymphoblastic leukemia cells were found in three normal unimmunized subjects. The sera were reactive with tumor cells from 514 (514 tested) acute lymphocytic leukemia patients, and three of 12 patients with acute myelocytic leukemia; they did not react with cells from two patients with acute monocytic leukemia, two patients with chronic lymphocytic leukemia, or two patients with

leukolymphosarcoma. The sera were also negative with normal lymphocytes from 52 different donors, lymphocytes from four acute lymphocytic leukemia patients in remission, and lymphocytes from a patient with Hodgkin's disease. Absorption studies suggested that the cytotoxic activity of the sera could be removed by incubation with leukemia cells but not by incubation with remission leukocytes.

- 5305 AN ANTIGEN IN HUMAN BREAST CANCER SERA RELATED TO THE MURINE MAMMARY TUMOUR VIRUS. (E.) Muller, M. (Inst. Path., Dresden, East Germany) and H. Grossmann. *Nature New Biol* 237:116-117, 1972.

Thirty-six sera from women with mammary carcinoma were reacted in micro-double-diffusion tests with three highly specific rabbit hyperimmune sera against the mammary tumor virus (MTV). Ten of 36 sera reacted with each of the three anti-MTV sera, whereas 35 sera from donors without mammary carcinoma failed to react with the anti-MTV sera. The factor detected in ten human breast cancer sera appeared to share common antigenicity with a constituent of the outer MTV-particle coat.

- 5306 THE FORMALINIZATION OF ANTIBODY TO TUMOR CELLS IN ALTERING THE IMMUNE RESPONSE. (E.) Ungaro, P. C. (Nat'l. Cancer Inst., Bethesda, Md.), W. P. Drake and M. R. Mardiney, Jr. *Cancer Res* 32(10):2241-2247, 1972.

EL-4 lymphoma cells from C57BL/6 mice were exposed to anti-C57BL/6 spleen cell sera or to anti-EL-4 sera from rabbits; formalin was added to mixtures to fix serum antibodies to lymphoma or spleen cell membranes. Formalin fixation of antibodies did not lead to nonspecific binding of antibody to the cell surface, nor did it alter the specificity or strength of immunofluorescence reactions of various antisera with formalinized cells. The amount of elution of radiolabeled antibody from formalinized EL-4 cells was observed. The proportion of total radiolabel that eluted from formalinized tumor cells was much greater than the proportion that eluted from cells that did not have antibody fixed to the membrane. In related experiments, rabbits were immunized with formalin-fixed EL-4 or C57BL/6 spleen cells and their sera were examined for cytotoxicity for EL-4 or spleen cells. Sera from rabbits immunized with formalin-fixed cells had relatively high titers of cytotoxic activity to EL-4 cells and C57BL/6 spleen cells. Sera from rabbits immunized with formalinized EL-4 or C57BL/6 spleen cells which had been preincubated with anti-C57BL/6 spleen antibody had a markedly reduced titer against EL-4 and C57BL/6 cells.

- 5307 REJECTION OF ASCITES TUMOR ALLOGRAFTS: I. ISOLATION, CHARACTERIZATION, AND *IN VITRO* REACTIVITY OF PERITONEAL LYMPHOID EFFECTOR CELLS FROM BALB/c MICE IMMUNE TO EL4 LEUKOSIS. (E.) Berke, G.

(5308-5312)

(Duke U. Med. Ctr., Durham, N.C.), K. A. Sullivan and B. Amos. *J Exp Med* 135(6):1334-1350, 1972.

BALB/c mice were inoculated i.p. or s.c. with EL-4 mouse leukemia cells. Ten days later, cells were harvested from thymus, lymph nodes, Peyer's patches, spleen, blood and peritoneal cavity, and tested for their cytolytic effect on ^{51}Cr -labeled EL-4 target cells *in vitro*. In mice given EL-4 i.p., peritoneal exudate cells (PEC) were much more cytolytic than the cells from other sites; however, in mice given EL-4 cells s.c., PEC were relatively inactive against target cells, and spleen and blood cells were most active. Most cytolytic activity of PEC cells resided in nonadherent as opposed to adherent cells; and most of the active nonadherent cells were lymphocytes rather than macrophages. Trypsin treatment of PEC cells temporarily abolished the cytolytic activity of the cells.

5308 KARYOTYPIC, VIROLOGIC, AND IMMUNOLOGIC ANALYSES OF TWO CONTINUOUS LYMPHOCYTIC LINES ESTABLISHED FROM NEW ZEALAND BLACK MICE: POSSIBLE RELATIONSHIP OF CHROMOSOMAL MOSAICISM TO AUTOIMMUNITY. (E.) Lerner, R. A. (Scripps Clin. Res. Fdn., La Jolla, Calif.), F. Jensen, S. J. Kennel, F. J. Dixon, G. Des Roches and U. Francke. *Proc Nat Acad Sci USA* 69(10):2965-2969, 1972.

Two lymphoid cell lines derived from a spontaneous NZB mouse fibrosarcoma and from an NZB spleen, resp., were examined. Fibrosarcoma-derived cells (SCRF60_A) produced budding C-type virus particles with buoyant densities of $1.16 \text{ g} \times \text{cm}^{-3}$. These particles exhibited 70S viral RNA, and RNA-dependent DNA polymerase. The virus from SCRF60_A cells infected NRK, NZB embryo, (NZB x NZW)_{F1} embryo, (NZW x NZW)_{F1} embryo, and BALB/c 3T3 cells, but did not infect NIH Swiss cells. The θ antigen was present on surfaces of spleen-derived cells, but was not seen on tumor-derived cells. Both cell lines showed chromosomal abnormalities, including an extra telocentric.

5309 SUSCEPTIBILITY AND RESISTANCE TO VIRAL LEUKEMOGENESIS IN THE MOUSE: IV. MECHANISMS OF HOST RESISTANCE TO LEUKEMIA EXPRESSION. (E.) Tennant, J. R. (Sloan-Kettering Inst., New York, N.Y.). *J Nat Cancer Inst* 49(5):1257-1267, 1972.

C57BR/cd mice were injected i.p. with 0.2 ml of B/T-L or BR-Bc mouse leukemia virus when one to four days old and challenged one to five months later with 10^3 cells of a transplantable C57BR/cd leukemia. Infant C57BR/cd mice were very susceptible to leukemia induction by BR-Bc virus. At six wk of age, only 6% of virus-inoculated mice rejected tumor cell transplants. By five months of age 34% of mice inoculated as infants with BR-Bc virus rejected tumor cell transplants. In contrast, infant mice resisted leukemia induction by B/T-L virus. By four wk of age, 50% of B/T-L-inoculated mice resisted tumor transplants and by five months, 95% rejected transplants. When mice were inoculated with BR-Bc virus as adults, there was moderate

resistance to viral leukemia induction; 90% of these mice rejected transplants four wk after virus inoculation. Adult mice were totally resistant to induction of leukemia by B/T-L virus, though only 12% of B/T-L-treated mice resisted tumor transplants.

5310 *IN VIVO* STUDIES OF THE ROLE OF CYTOTOXIC T CELLS IN TUMOR ALLOGRAFT IMMUNITY. (E.)

Freedman, L. B. (Swiss Inst. Exp. Cancer Res., Lausanne), J.-C. Cerottini and K. T. Brunner. *J Immunol* 109(6):1371-1378, 1972.

Intraperitoneal growth of (DBA/2) P-815 mastocytoma cells in heavily irradiated (800 and 950 R) C3H male and female mice was prevented for at least 21 days by i.v. or i.p. injection of syngenic immune, but not normal, spleen cells. Tumor growth was also inhibited in mice receiving a pure population of immune thymus-derived (T) cells which were free of bone marrow-derived (B) lymphocytes and allo-antibody-forming cells. No protection was achieved with transfer of immune B cells (i.e., immune spleen cells treated with anti- θ serum and C). Intravenous injection of immune T cells also prevented s.c. growth of P-815 cells in heavily irradiated C57BL/6 mice. It was concluded that immune T cells played a primary role in the rejection of allogenic tumor cells in heavily irradiated C3H and C57BL/6 mice.

5311 ANTI-HUMAN IMMUNOGLOBULIN G ACTIVITY OF MEMBRANE-BOUND MONOCLONAL IMMUNOGLOBULIN M IN LYMPHOPROLIFERATIVE DISORDERS. (E.) Preud'homme, J. L. (Hosp. St.-Louis, Paris, France) and M. Seligmann. *Proc Nat Acad Sci USA* 69(8):2132-2135, 1972.

Lymphocytes from blood and bone marrow of Waldenström's macroglobulinemia patients and from blood of chronic lymphocytic leukemia patients were reacted with antisera to the five immunoglobulin polypeptide chains (μ , γ , α , κ , or λ) and studied by membrane immunofluorescence. Freshly drawn lymphocytes showed membranes positive for γ , κ , γ and μ chain determinants; all four determinants being present on single cells. Surface immunoglobulins were redistributed by antibody treatment or by trypsinization of cells, after which the presence of a newly synthesized monoclonal IgM immunoglobulin was observed. This IgM had features of an antibody to human IgG. It specifically bound normal human IgG molecules devoid of aggregated material. IgG molecules could be removed from cell surfaces by lowering the pH.

5312 QUANTITATION OF *IN VIVO* GROWTH OF PLASMA-CYTOMA X5563 BY IMMUNOASSAY FOR ITS PARAPROTEIN WITH INDIVIDUAL ANTIGENIC SPECIFICITY. (E.) Yutoku, M. (Osaka U. Med. Sch., Japan), H. Senoh, S. Watanabe, Y. Matsuoka and M. Kitagawa. *J Nat Cancer Inst* 49(5):1395-1402, 1972.

An experimental tumor model system was designed to

follow quantitatively the *in vivo* fate of tumor cells. A transplantable plasmacytoma, X5563 of the C3H/He mouse, was inoculated s.c., i.p., or i.v. into syngeneic C3H/He mice and allogeneic C57BL and ddO mice. The serum concentration of the paraprotein γG_{2a} , produced by X5563 cells, was quantitated by an immunoassay with the use of antiserum against the individual specific determinant(s) of X5563 γG_{2a} . The level of the X5563 γG_{2a} in serum of C3H mice receiving s.c. the X5563 cells increased progressively as the tumor grew and correlated well with the increase in tumor diameter. The X5563 γG_{2a} level in serum of allogeneic mice increased only temporarily and then decreased; it also correlated with the growth and regression of tumors, as assessed by the diameters of the tumors. Thus, the fate of tumor cells *in vivo* can be assessed by the estimation of the level of X5563 γG_{2a} in serum. This method revealed that the growth of X5563 inoculated i.v. was markedly suppressed, even in the syngeneic C3H mice (temporarily early after inoculation) and completely and permanently suppressed in the allogeneic ddO mice. This assay system may be valuable for the study of such problems as metastases, tumor immunity, and carcinostatic agents.

- 5313 EFFECTS OF INFANT THYMECTOMY AND ANTILYMPHOCYTE SERUM ON XENOTRANSPLANTATION OF A HUMAN LEUKEMIA IN THE HAMSTER. (E.) Mark, L. P. (Harvard Med. Sch., Boston, Mass.) and R. A. Adams. *Cancer Res* 32(7):1580-1583, 1972.

The effects of antilymphocyte serum (ALS) (0.05 ml i.p.) and neonatal thymectomy on the transplantability of a human leukemia (H-HM-1 tumor) were studied in hamsters of varying ages. Unthymectomized hamsters received one of three ALS regimes: ALS at time of tumor inoculation, ALS at birth, or ALS at birth and again at time of tumor inoculation. Thymectomized hamsters received no ALS, ALS at time of tumor inoculation, or ALS on day of thymectomy and on day of tumor inoculation. Multiple doses of ALS prolonged the period of susceptibility to tumor implantation as compared with a single dose at time of tumor inoculation. Neonatal thymectomy did not substitute for ALS administration, but a combined program of thymectomy and multiple ALS treatment greatly depressed host resistance to the tumor xenograft, allowing successful transplantation as late as 20 days after birth. These results suggest that a thymic-dependent immune mechanism is involved in the rejection of a human tumor xenograft by hamsters.

- 5314 STRUCTURAL DIFFERENCES IN MOUSE IgA MYELOMA PROTEINS OF DIFFERENT ALLOTYPES. (E.) Warner, N. L. (Hall Inst. Med. Res., Melbourne, Australia) and J. J. Marchalonis. *J Immunol* 109(4):657-661, 1972.

Sera from BALB/c, NZB and (BALB/c x NZB) F_1 mice bearing plasma cell tumors were subjected to starch block gel electrophoresis or DEAE chromatography to purify IgA myeloma proteins. The proteins were

examined electrophoretically for the presence of L-H disulfide bonds. No disulfide bonds were detected in IgA proteins from three BALB/c mice; however, IgA proteins from each of three NZB mice and from five of ten hybrid mice contained L-H disulfide bonds. IgA proteins were also tested for reactions in the Ig-2^e allotype antigen-specific assay. All BALB/c proteins failed to react, while all NZB proteins and five of ten hybrid proteins did react. The reactive proteins from hybrid mice were the same proteins that showed no dissociation in tests for L-H disulfide bonds.

- 5315 SYNERGISTIC INHIBITION OF MAMMARY CARCINOMA TRANSPLANTS IN A-STRAIN MICE BY ANTI-TUMOUR GLOBULIN AND *C. PARVUM*. (E.) Woodruff, M. F. A. (Dept. Surg., U. Edinburgh, Scotland) and M. P. Inchley. *Br J Cancer* 25(3):584-593, 1971.

Female A/HeJ mice were injected s.c., i.v. or i.p. with *C. parvum* two days before receiving an s.c. intrastrain transplant of mouse mammary carcinoma cells. Tumor growth was inhibited to a moderate extent by i.v. injection of *C. parvum*. Intra-peritoneal injection gave similar results but s.c. injection was less effective. Incubation of tumor cells with antitumor globulin (ATG) prepared from rabbits immunized with tumor cells appeared to facilitate tumor growth in mice not pretreated with *C. parvum*. However, incubation of tumor cells with ATG potentiated the tumor-inhibiting effect of *C. parvum* in treated mice. By 60 days after transplantation, tumors in mice given tumor cells preincubated with ATG, but not given *C. parvum*, had a mean diameter of 11 mm, while tumors in mice given ATG-treated cells and pretreated with *C. parvum* had mean tumor diameters of 6 mm. The synergistic effect of ATG and *C. parvum* is discussed in relation to phagocytic activity in A/HeJ mice.

- 5316 TUMORIGENESIS IN STRAIN DW/J MICE AND INDUCTION BY PROLACTIN OF THE GROUP-SPECIFIC ANTIGEN OF ENDOGENOUS C-TYPE RNA TUMOR VIRUS. (E.) Chen, H. W. (Jackson Lab., Bar Harbor, Me.), H. Meier, H.-J. Heiniger and R. J. Huebner. *J Nat Cancer Inst* 49(4):1131-1137, 1972.

The dwarf mutation (gene symbol *dw*), maintained in the inbred strain DW/J, causes primary anterior pituitary endocrine defects. These defects were remedied by prolactin, which reversed growth retardation and organ hypoplasia or atrophy, stimulated RNA and protein synthesis, and also induced the intraspecies group-specific antigen (gs-AG) of endogenous C-type RNA tumor virus. No tumors were observed in dwarf mice. In young normal littermates, prolactin caused precocious appearance of gs-AG. Thus prolactin increased expression of genetic information, including viral gs-AG. Both mesenchymal and epithelial tumors occurred in DW/J heterozygotes (*dw*/+) and homozygous normal (+/+) mice. The development of two types of tumors in six mice indicated separate and possibly independent events of malignant transformation. Normal mice of either genotype had a high incidence (85%) of gs-AG expres-

(5317-5321)

sion, which increased with age. The closely associated development of reticulum cell sarcomas and gs-AG in these mice indicated an etiologic relationship.

- 5317 MEASUREMENT OF THE ANTITUMORAL IMMUNE REACTIONS AGAINST A STRAIN-SPECIFIC CHEMICALLY-INDUCED SARCOMA IN SYNGENEIC AND F₁ HYBRID MICE. (E.) Oth, D. (INSERM, Vandoeuvre, France), M. Donner and C. Burg. *Eur J Cancer* 7(5):479-482, 1972.

Swiss/B mice and (Swiss/B x C3H/He)F₁ hybrids were immunodepressed by exposure to whole body irradiation (500 rads); other mice were specifically immunized against the dibenzanthracene-induced rhabdomyosarcoma TP10, a tumor which is specific to Swiss/B mice. Transplantability of TP10 challenge grafts in immunodepressed, specifically immunized, and untreated Swiss/B and hybrid mice was observed. Percentages of tumor takes in immunodepressed and immunized Swiss/B mice were not significantly different from percentages of takes in untreated Swiss/B mice. In hybrid mice, however, immunodepression markedly enhanced tumor transplantability, while specific immunization markedly diminished it. Similar differences between Swiss/B and hybrid mice were seen when mean survival time of tumor-bearing mice was observed.

- 5318 UMBILICO-PLACENTAL ANTIGENS AND MALIGNANT NEOPLASMS. (E.) Mori, W. (Tokyo Med. Dent. U., Japan) and H. Asakawa. *Bull Tokyo Med Dent Univ* 18(4):281-293, 1971.

Rabbits were inoculated with homogenates of human placental or umbilical cord tissue to obtain anti-placental and anti-umbilical cord tissue antisera. Antigen-antibody reactions between the anti-placental antiserum and sera from 576 patients with various diseases were observed using the micro-Ouchterlony method. A relatively high incidence of positive reactions was noted with cases of malignant tumors (57.5%), leukemia (63.65%), myocardial infarction (41.2%) and hepato-biliary diseases (43.3%). Among the malignant tumors tested, multiple myeloma and malignant lymphoma showed an extremely high incidence of positive reactions. Other neoplasms with a high incidence of positive reactions were tumors of the stomach, colon, liver and pancreas. In general, sera from patients with advanced malignant tumors showed positive reactions more frequently than sera from patients in the early stage of cancer. The active factor was located in the β -area by immunoelectrophoresis. Antigen analysis using a double diffusion method on agar plate showed a similarity between umbilical cord and placental tissue extracts.

- 5319 SMOOTH MUSCLE ANTIBODY IN MALIGNANT DISEASE. (E.) Whitehouse, J. M. A. (Chester Beatty Res. Inst., Sutton, England), E. J. Holborow, G. H. Fairley and P. Alexander. *Novu Rev Fran Hemato* 12(3):383-386, 1972.

Indirect immunofluorescence was used to detect smooth

muscle autoantibody (SMA) and anti-nuclear factor (ANF) in serum of 113 patients with malignant disease and in 46 healthy controls. Malignant patients included cases of malignant melanoma, neuroblastoma, and bronchial, mammary and ovarian carcinoma. Sixty-eight percent of these patients had SMA-positive sera, while 20% of healthy subjects' sera were SMA-positive. SMA occurred at higher titers in cancer patients' sera than in normal sera. ANF was found in 27% of cancer patients and in one of the 46 healthy controls. A new IgG antibody was seen in seven cases (six from cancer patients and one from a normal subject); this agent stained liver in a pattern similar to that produced by SMA.

- 5320 FURTHER PURIFICATION OF PERCHLORATE-SOLUBLE ANTIGENS FROM HUMAN COLONIC CARCINOMATA. (E.) Turner, M. D. (U. Rochester Sch. Med. Dent. N.Y.), T. A. Olivares, L. Harwell and M. S. Kleinman. *J Immunol* 108(5):1328-1339, 1972.

Carcinoembryonic antigen (CEA) was isolated from human colonic carcinoma by perchloric acid extraction and its structure and determinants were studied. Radioiodine-labeled CEA (¹²⁵ICEA) behaved like a homogenous substance in G-200 Sephadex gel filtration, electrofocusing, and sucrose gradient centrifugation. On cesium chloride density gradient ultracentrifugation, however, ¹²⁵ICEA showed three components with densities of 1.47 (UCP-1), 1.42 (UCP-2) and 1.28 (UCP-3), resp. UCP-2 appeared to represent purified CEA; it reacted vigorously with absorbed goat and rabbit anti-CEA sera in precipitation tests. UCP-1 reacted, though not so vigorously as UCP-2, with rabbit and goat anti-CEA sera and with human anti-A blood group antiserum. UCP-2 reacted only weakly with human anti-A. The precipitation of UCP-1 and UCP-2 by human anti-A serum was almost completely abolished by microgram quantities of mixed A and B blood substances. The A and B substances had no effect on the precipitation of UCP-2 by goat or rabbit anti-CEA anti-serum, but they markedly inhibited precipitation of UCP-1 by both these sera.

- 5321 THE TUMOR IMPRINT TECHNIQUE FOR DEMONSTRATING SV40 T ANTIGEN BY IMMUNOFLUORESCENCE. (E.) Diamandopoulos, G. T. (Harvard Med. Sch., Boston, Mass.) and M.-F. McLane. *Proc Soc Exp Biol Med* 141(1):62-66, 1972.

The tumor imprint technique has been adapted to the indirect immunofluorescence test for SV40 tumor (T) antigen in tumor tissues. Leukemia, lymphosarcoma, reticulum cell sarcoma and other tumors produced in hamsters by SV40 inoculation were excised and imprinted by applying the cut surface of the tumor to a cover glass. Indirect immunofluorescence tests were performed on these imprints using sera from hamsters bearing tumors known to contain SV40 T antigen. T antigen could be demonstrated readily in imprints from tumors and in imprints from lymph nodes and other organs. The advantages of this method of

demonstrating SV40 T antigen include the preservation of cytoplasmic and nuclear features of tumor cells and the preservation of *in vivo* spatial relationships between tumor cells and normal cells. The new tumor imprint T antigen test also obviates the necessity of culturing cells to be tested; this test is feasible even when it is impossible to culture SV40-transformed cells.

- 5322 IMMUNODEPRESSIVE EFFECT OF GRAFFI LEUKEMIA VIRUS. (Rus.) Ancheva, M. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow). *Vopr Virusol* 16(6):661-665, 1971.

The effects of Graffi leukemia virus on cellular and humoral immunological responses were studied in mice. Newborn BALB/c mice received s.c. injections of 0.2 ml 10% extracellular spleen extract from mice of the same line infected with Graffi leukemia. Four-week old mice received i.p. infusions of $2-3 \times 10^7$ leukemia cells. These mice were immunized with sheep 2×10^8 erythrocytes given i.p. at intervals after infection. The antibodies to sheep erythrocytes (19S- and 7S-hemagglutinins) were determined 4, 7, and 10 days postimmunization. The antibody-forming cells were determined by the Gerne and Nordin method. Graffi leukemia virus showed immunodepressive effects in these mice. In control mice, the antibody-forming cells ($652/10^6$ cells) and antibody titers (6.5) were maximal on the 4th day after immunization, while they were suppressed in leukemia-infected mice ($6/10^6$ cells and 1.4, resp.). The antibody-forming cells of the infected mice were 1% of those of the control animals. Thus, Graffi leukemia virus suppresses cellular and humoral immunity.

- 5323 A FETAL ANTIGEN ASSOCIATED WITH HUMAN NEOPLASIA. (E.) Edynak, E. M. (Sloan-Kettering Inst., New York, N.Y.), L. J. Old, M. Vrana and M. P. Lardis. *New Engl J Med* 286(22): 1178-1183, 1972.

Serum from patients with malignant and nonmalignant diseases was reacted in micro-Ouchterlony immunodiffusion tests with tissue antigens prepared from the same group of subjects. The serum of eight of 1518 cancer patients contained precipitating antibody defining a new antigen associated with human neoplasia. Named γ -fetoprotein (FP) because of its electrophoretic mobility and its occurrence in the serum and tissues of the normal fetus, the antigen was present 169 of 225 benign and malignant tumors, the serum of 23 of 210 cancer patients tested and two of 101 nonneoplastic human tissues. It was not present in any normal human tissue or in adult human serum. In immunoelectrophoresis tests, γ -FP showed a mobility similar to that of human fetal serum and fetal calf serum, and also to those of rectal, breast and osteogenic malignant tumors.

- 5324 INFLUENCE OF NEONATAL THYMECTOMY UPON THE CELL-MEDIATED TUMOR-SPECIFIC IMMUNITY

IN ROUS SARCOMA VIRUS TUMORIGENESIS IN RATS. (E.) Borum, K. (Inst. Path., U. Lund, Sweden) and N. Jonsson. *Cellular Immunol* 3:22-32, 1972.

Rats were thymectomized within 24 hr after birth. At four wk, some thymectomized and unthymectomized rats were inoculated with Schmidt-Ruppin Rous sarcoma virus (SR-RSV) preparation. The production of thoracic duct lymphocytes (TDL) and the yield of lymph node cells (LNC) were observed in these rats; the colony-inhibiting activity (CI) of TDL and LNC from rats was also observed. Thymectomy markedly reduced TDL output in rats without SR-RSV-induced sarcomas and in rats with small sarcomas; TDL output was not as affected in unthymectomized rats and in thymectomized rats with small sarcomas. LNC yield was not significantly changed by thymectomy. In rats without SR-RSV-induced lesions, TDL from thymectomized and unthymectomized rats had similar CI ability. However, thymectomy reduced CI ability of TDL from rats with large sarcomas (four of nine thymectomized rats showed a CI effect) relative to the CI ability of unthymectomized rats with large sarcomas (11 of 13 unthymectomized rats showed a CI effect).

- 5325 ACUTE LEUKEMIA IN IDENTICAL TWINS: SEARCH FOR VIRAL AND LEUKEMIA-ASSOCIATED ANTIGENS. (E.) Levine, P. H. (Nat'l. Cancer Inst., Bethesda, Md.), R. B. Herberman, E. B. Rosenberg, P. D. McClure, A. Roland, R. J. Pienta and R. C. Y. Ting. *J Nat Cancer Inst* 49(4):943-945, 1972.

Ten sets of identical twins, one member of each pair having leukemia, were studied for the presence of leukemia-associated antigens. All patients except one were less than 16 yr old at diagnosis. Three immunologic tests, lymphocyte cytotoxicity, skin tests for delayed hypersensitivity, and immunofluorescence studies were performed. Susceptibility of skin fibroblasts to transformation by simian virus 40 was measured as a possible indicator of genetic predisposition to development of leukemia. In seven families, lymphocytes from family members and unrelated controls were cytotoxic for cells from the leukemic twin but not for cells from the normal twin. Delayed hypersensitivity reactions were elicited by extracts of patients' leukemic cells but not by extracts of remission cells or the normal twins' cells.

- 5326 BEHAVIOR OF IMMUNOGLOBULINS IN MALIGNANT LYMPHOGRANULOMATOSIS AND THYMOMA. (E.) Kraj, M. (Inst. Hematol., Warsaw, Poland) and S. Ciesluk. *Arch Immunol Therap Exp (Warsz)* 20:235-241, 1972.

Immunoglobulin levels were determined in blood sera from 36 patients with malignant lymphogranulomatosis and in one patient with thymoma. Mean γ -fraction levels in lymphogranulomatosis patients were lower than in normals, but the difference barely achieved statistical significance. Mean IgG levels in lymphogranulomatosis patients were elevated relative to normal values (14.5 ± 5 mg/ml for patients and 11.8

(5327-5331)

± 2.48 mg/ml for normals). Mean IgA values for lymphogranulomatosis patients were within normal limits. IgM levels were reduced in 50% of patients, though the mean IgM level for patients was normal. Hypogammaglobulinemia was seen in four cases. In one case, low serum IgG and IgM values were associated with deposits of IgG and IgM at the dermoepidermal boundary. In another case, proliferation of hemacytoblasts and young reticulum cells was seen in bone marrow. The thymoma patient showed low γ -fraction values before removal of the tumor. After thymectomy, γ -fraction values continued to be depressed, as did levels of the three immunoglobulins. After splenectomy, all three immunoglobulins began to increase.

5327 CARCINOEMBRYONIC ANTIGEN: SYNTHESIS BY A CONTINUOUS LINE OF ADENOCARCINOMA CELLS.

(E.) Egan, M. L. (City Hope Natl. Med. Ctr., Duarte, Calif.) and C. W. Todd. *J Nat Cancer Inst* 49(3):887-889, 1972.

Human colonic adenocarcinoma cells were incubated for two wk to three months. After incubation, cells were treated with perchloric acid (PCA) and assayed for carcinoembryonic antigen (CEA). The culture medium of the carcinoma cells contained 17 ng/ml CEA activity after seven days of culture and 300 ng/ml after 29 days. Tenfold more CEA was found in culture medium supernatants treated with 1.25 M $(\text{NH}_4)_2\text{SO}_4$ than in carcinoma cell PCA precipitates. The CEA active material in culture fluids was a molecule which was stable in 1 M PCA and soluble in 1.25 M $(\text{NH}_4)_2\text{SO}_4$. This material eluted from a G200 column in the position as CEA extracted from tumor cells. Other tumor cell lines, including a laryngeal epidermoid carcinoma and a mesothelioma, were CEA-negative; a cervical adenocarcinoma cell line was CEA-positive.

5328 SEPARATION OF TWO DISTINCT TUMOR-ASSOCIATED ANTIBODIES IN THE SERUM OF MELANOMA PATIENTS.

(E.) Lewis, M. G. (Dept. Path., Memorial U. Newfoundland, St. John's, Canada) and T. M. Phillips. *J Nat Cancer Inst* 49(3):915-917, 1972.

Cytoplasmic and surface membrane reactions in human malignant melanoma were studied by cross-absorption, immunofluorescence and immunodiffusion techniques. Two different melanoma cell suspensions and their autologous positive sera were used to separate antibodies in the sera so that the common antibody against cytoplasmic contents was absorbed out, thus leaving a patient-specific antibody directed against the individual cell membrane. The results confirm the relative specificity of the antibody/antigen reaction in human malignant melanoma and offer a method for study of the relationship between the two antibodies and circulating antigen during the development of melanoma.

5329 THE SV40 S ANTIGEN: A CARCINOEMBRYONIC-TYPE ANTIGEN OF THE HAMSTER? (E.) Berman,

L. D. (Boston City Hosp., Mass.). *Int J Cancer* 10(2):326-30, 1972.

Further evidence is presented that the membrane-associated S antigen, originally demonstrated in tumor-bearing hamsters, is not identical to the SV40 T antigen. Indirect membrane fluorescent antibody tests revealed that, in addition to SV40-induced hamster tumor and SV40-transformed hamster embryo and thyroid cells, a variety of non-SV40-exposed hamster cell lines were also positive for S antigen. The reactive cells included transformed lines induced by heterologous DNA (adenovirus) and RNA (Murine Sarcoma) viruses, as well as four different lines of BHK 21 cells and a line of hamster embryo cells that were never exposed to virus. Anti-S antiserum titrated equally well on both the nonvirus-exposed BHK and the SV40-induced tumor cells. Absorption of anti-S antiserum to BHK, hamster tumor or hamster embryo cells significantly reduced activity to the hamster tumor cells. No S antigen was detected in cells from full-term embryos, newborn or adult hamsters or in SV40- or adenovirus-transformed mouse embryo cells.

5330 SERUM-MEDIATED BLOCKING OF CELL-MEDIATED ANTI-TUMOR IMMUNITY IN A MELANOMA PATIENT: ASSOCIATION WITH BCG IMMUNOTHERAPY AND CLINICAL DETERIORATION. (E.) N. L. Levy, (Duke U. Med. Ctr., Durham, N.C.), M. S. Mahaley, Jr. and E. D. Day.

Int J Cancer 10(2):244-248, 1972.

Evidence is presented for a close temporal association of BCG inoculation, the appearance of a blocking factor and the accelerated deterioration of a 66-year-old male patient with melanoma. Microcytotoxicity tests showed that on two occasions prior to BCG injection, the patient's lymphocytes were significantly cytotoxic to his tumor cells but not to autogenous or allogenic fibroblasts. The patient's serum showed no ability to block the *in vitro* cytotoxic effects of his lymphocytes. Three wk after BCG administration, the patient's lymphocytes were still cytotoxic, but his serum completely blocked their *in vitro* tumoricidal effects. Although this single case does not warrant the discontinuance of BCG therapy, its future use should be carefully monitored by adequate *in vitro* procedures.

5331 PREVALENCE OF THE GROUP-SPECIFIC (gs) ANTIGEN AND INFECTIOUS VIRUS EXPRESSIONS

OF THE MURINE C-TYPE RNA VIRUSES DURING THE LIFE SPAN OF BALB/cCr MICE. (E.) Peters, R. L. (Microbiol. Assoc., Inc., Walkersville, Md.), J. W. Hartley, G. J. Spahn, L. S. Rabstein, C. E. Whitmire, H. C. Turner and R. J. Huebner. *Int J Cancer* 10(2):283-289, 1972.

Incidences of C-type RNA tumor-virus gs antigen and infectious virion expression were determined, by complement fixation and CoMuL tests, resp., in BALB/cCr mice at various stages throughout their life span. The incidence of gs antigen was low (2.5%) in mice younger than six months, but increased progressively thereafter to 71% in mice

older than 24 months. The incidence of infectious virus isolated on mouse embryo cell cultures showed a similar pattern, being low (10%) in mice prior to six months and rising rapidly thereafter to a relatively stable value of 46-62% which was maintained for the rest of the lifetime. Eighteen of 19 isolations made prior to one yr were made on NIH Swiss mouse embryo cells as opposed to BALB/c mouse embryo cells. The number of isolations on BALB/c cells increased in older mice but did not overtake those made on NIH Swiss mice cells until after 24 months of age. Isolations from the spleens of malignant tumor-bearing mice were slightly more frequent than those from spleens of normal or benign tumor-bearing mice.

- 5332 EMBRYONIC ANTIGEN EXPRESSION IN CHEMICALLY INDUCED RAT HEPATOMAS AND SARCOMAS. (E.) Baldwin, R. W. (Cancer Res. Campaign Labs., U. Nottingham, England), P. Graves and B. M. Vose. *Int J Cancer* 10(2):233-243, 1972.

Indirect membrane immunofluorescence tests using sera from multiparous rats were employed to detect embryo-specific antigens on the surface of three 4-dimethylaminoazobenzene-induced rat hepatomas and two of four 3-methylcholanthrene-induced rat sarcomas. Sera from age-matched control virgin rats were nonreactive. These results were confirmed by tests in which the sera from multiparous rats showed complement dependent cytotoxicity for plated target tumor cells. Lymph node cells from multiparous rats also exhibited cytotoxicity when compared with the effects of cells from the virgin controls. These embryonic antigens could be demonstrated on embryonic cells but not on cultured normal adult rat liver cells or lung fibroblasts. The tumor-associated embryonic antigens were common to both hepatomas and sarcomas. Thus, they differ from the individually distinct tumor antigens responsible for eliciting specific immunologic responses in hosts.

- 5333 ON THE NATURE OF THE SV40 VIRAL ANTIGEN INDUCED IN BSC₁ TRANSFORMED CELLS: BRIEF REPORT. (E.) Margalith, M. (Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel), E. Margalith and G. Spira. *Arch Gesamte Virusforsch* 36:398-400, 1972.

Monkey anti-SV40 serum fractionated by two methods was used in direct immunofluorescence on BSC₁ cells infected with SV40 and on BSC₁ transformed cells heated to 45 C for 30 min to induce synthesis of SV40 viral antigen. After filtration of the serum through Sephadex G 25, the γ -globulin fraction used for immunofluorescence was obtained by fractionation of serum on DEAE cellulose at pH 7.2 or by fractionation of dialyzed serum on DEAE cellulose at pH 9.6-7.2. Only the fraction obtained at pH 9.6 showed fluorescence in infected but not in transformed heat-treated cells. In infected cells there was no difference in the percentage of cells stained with anti-SV40 serum fractionated by the two methods; a marked difference was evident in the percentage of stained transformed

cells. These findings indicate that two types of antibody are presented in monkey anti-SV40 serum. The fraction obtained at pH 9.6 reacts with the viral antigen synthesized during the productive cycle of SV40 virus but not with the antigen induced by heating of the transformed cells. The fraction obtained at pH 7.2 reacts with both the viral antigen synthesized during the productive cycle and that induced by heating of the transformed cells.

- 5334 CIRCULATING LEVELS OF IMMUNOGLOBULIN E IN PATIENTS WITH CANCER. (E.) Jacobs, D. (Benenden Chest Hosp., Kent, England), M. Hourfi, J. Landon and T. G. Merrett. *Lancet* 2(7786):1059-1061, 1972.

Sera were collected from 100 healthy subjects, from 200 untreated cancer patients, from 200 cancer patients given cyclophosphamide, and from 50 allergy patients. Half the treated cancer patients had bronchial carcinoma; the others had myeloma, prostate cancer, mammary cancer, etc. A solid-phase radioimmunoassay and a radial immunodiffusion test were used to quantitate IgE immunoglobulin in these patients. Mean IgE levels determined by radioimmunoassay were 215 U/ml serum for normals, 1060 U/ml for allergic patients, and 125 U/ml for treated cancer patients. Half the untreated cancer group had mean IgE levels of > 100,000 U/ml, the other half had very low IgE values. Results of radial immunodiffusion studies were in agreement with results of the radioimmunoassay for IgE in all groups except untreated cancer patients. These patients had almost undetectable IgE values using the radial immunodiffusion technique. Additional studies indicated that the high IgE values observed in untreated cancer patients by radioimmunoassay were an artefact due to the presence of a circulating inhibitor.

- 5335 α -FOETOPROTEIN IN RATS WITH HEPATOMAS INDUCED BY AFLATOXIN B₁. (E.) Kroes, R. M. (Natl. Cancer Inst., Bethesda, Md.), J. M. Sontag, J. H. Weisburger, P. M. Newberne and G. N. Wogan. *Nature* 240(5378):240-241, 1972.

Male rats were given aflatoxin B₁ in diet (100 parts/10⁹, group 1) or by gavage (1 mg total dose, group 2). Controls were given saline solution. Hepatocellular carcinomas developed in all of six rats in group 1 at 20 months, and in all of four in group 2 at 12 months. Controls developed no tumors. α -Fetoprotein was detected in sera of two group 1 rats and in sera of all four group 2 rats. This report represents the first observation of α -fetoprotein-positive sera in animals with aflatoxin B₁-induced hepatocellular carcinomas.

- 5336 LOCATION OF THE SECOND GENE REQUIRED FOR EXPRESSION OF THE LEUKEMIA-ASSOCIATED MOUSE ANTIGEN G_{1X}. (E.) Stockert, E. (Sloan-

5337-5341)

ettering Inst. Cancer Res., New York, N.Y.), H. Sato, K. Itakura, E. A. Boyse, L. J. Old and J. Hutton. *Science* 178(4063):862-863, 1972.

The location of the *Gv-2* gene locus was established in a three-point cross with *Gpi-1* (glucose phosphate isomerase) and *Hbb* (β chain of hemoglobin). *Gv-2*, along with *Gv-1*, controls G_{IX} , a cell surface antigen, found on thymocytes of some (i.e., G_{IX}^+) mouse strains and not on others. Murine leukemia virus causes G_{IX} antigen to be expressed on cells of genotypes which normally yield the G_{IX}^- phenotype, that is, on cells of mice lacking either the *Gv-1*⁺ allele or the *Gv-2*⁺ allele, or both. *Gv-1* had been located on linkage group IX, 36 U from *H-2*. *Gv-2* was located on linkage group I (chromosome 7), 33.6 \pm 5 U from *Hbb*, with the gene order: *Gpi*, *Hbb*, *Gv-2*.

5337 LEUKOCYTE ANTIGENS AND DISEASE. II. ASSOCIATION OF HL-A5 AND LYMPHOMAS. (E.) Rege, V. (Rhode Island Hosp., Providence), R. Patel and W. A. Briggs. *Am J Clin Pathol* 58(1):14-16, 1972.

Forty-three healthy persons and 42 patients with biopsy-proven lymphoma (including 20 with Hodgkin's disease) were typed for eight histocompatibility antigens in a standard lymphocyte cytotoxicity test. The two groups differed only with respect to the HL-A5 antigen. Hodgkin's disease patients and patients with other lymphomas had about twice the incidence of positive reactions with anti-HL-A5 antisera ($p < 0.05$) as did the normal controls. The association of an histocompatibility antigen with human lymphomas is analogous to the association of the H-2 mouse histocompatibility antigen with leukemia. Whether the increased susceptibility is due to a genetic factor or to a viral component as in the mouse, or to both, is unknown.

5338 GENETIC REGULATION OF THE THYMUS DEPENDENT HUMORAL IMMUNE RESPONSE IN LEUKEMIA PRONE AKR (H-2^k) AND NONLEUKEMIC C3H (H-2^k) MICE. DESCRIPTION OF GENETIC CONTROL OF THE IMMUNE RESPONSE AT THE LEVEL OF PROLIFERATION. (E.) Gottlieb, C. F. (Oak Ridge Grad. Sch. Biomed. Sci., Tenn.), E. H. Perkins and T. Makinodan. *J Immunol* 109(5):974-981, 1972.

Adult AKR and C3H mice, F₁ and F₂ offspring from matings of these strains, and AKR- and C3H-back-cross progeny were exposed to 800 R X-irradiation and inoculated i.v. with AKR spleen cells and sheep erythrocytes (SRBC). Spleen wt and plaque-forming cells (PFC) in spleen of irradiated recipients were observed on day six after inoculation. PFC responses and spleen wt values were low in AKR recipients and high in C3H recipients. PFC and spleen wt values in progeny groups fell between the AKR and C3H values. These results provide evidence that immunocompetent cell proliferation is under host gene control, and the evidence for a genetic defect in the AKR environment is consistent with a single, apparently non-H-2, autosomal gene locus.

5339 PHOSPHORYLASE: A NEW ISOZYME IN RAT HEPATIC TUMORS AND FETAL LIVER. (E.) Sato, K. (Temple U. Sch. Med., Philadelphia, Pa.), H. P. Morris and S. Weinhouse. *Science* 178(4063):879-881, 1972.

Rat liver and skeletal muscle tissue, and Novikoff ascites hepatoma and Morris hepatoma 20 tissue, were homogenized and centrifuged and subjected to isoelectric focusing. In hepatoma tissues, a third form of glycogen phosphorylase isozyme was discovered; this isozyme differed kinetically from the rat liver type and immunologically from the rat muscle type. The tumor form phosphorylase isozyme was present in both a and b forms. Morris hepatoma possessed both tumor and adult liver form isozymes, as did fetal rat liver. The adult liver and tumor forms of the isozyme failed to react with antibody to rat muscle isozyme. These findings are another example of suppression of isozymes of adult liver coupled with the appearance of fetal isozymes in hepatomas.

5340 ALTERATION OF SKIN IN GROSS LEUKEMIA. III. QUANTITATION OF THE ROLE OF TUMOR CELLS. (E.) Mariani, T. (Pediat., Path., Radiat. Res. Lab., U. Minnesota, Minneapolis), Y. Maruyama and R. A. Good. *J Nat Cancer Inst* 48(2):363-366, 1972.

Normal (C3H/Bi x DBA/2)F₁ mice were transplanted with normal syngenic skin. Twenty-four hr later, suspensions containing log₁₀ titrations of 10⁶, 10⁵, 10⁴, 10³, 10², 10¹ and 4 tumor Gross lymphoma ascites cells were injected directly into the skin graft. The frequency of graft rejection in animals receiving titrations of 10⁶ to 10³ cells was 60-100% with mean rejection times of 14-16 days. The animals given injections of 10² tumor cells showed a lowered rejection rate (40%) and a longer mean rejection time (18 days). No animal injected with 10¹ and 4 tumor cells rejected the graft. As the number of tumor cells injected decreased, not only did the rejection rate decrease, but tumor development took longer and host survival time increased. The critical point for inducing skin-graft rejection was between 10-100 tumor cells. Some animals were given injections of the cell-free filtrate from leukemic tissues and all of these accepted the skin graft without developing tumors at the graft site. The data indicated that graft rejection is possibly due to some response elicited by the tumor cell itself.

5341 HOST RESPONSE DURING THE LATENT PERIOD AND THE GROWTH OF AN IMMUNOLOGICALLY INDUCED MOUSE LYMPHOMA. (E.) Krüger, G. F. (Nat'l. Cancer Inst., Bethesda, Md.). *Beitr Pathol* 146(2):132-144, 1972.

Female BALB/c and DBA/2N mice were injected i.p. with bovine serum albumin (BSA) and fed 15 mg/kg/day azathioprine (immunosuppressant). Lymphosarcoma development and serum anti-BSA antibody levels were observed.

Malignant generalized lymphosarcoma (stem cell type) developed in thymuses of 20% of BALB/c mice given BSA and azathioprine, and in 66% of thymuses of DBA mice given this treatment. Lymphosarcoma incidence among untreated rats did not exceed 4%. Circulating antibody titers were elevated during tumor latent periods, but no cellular immune reaction to the BSA antigen was detected. The impairment of cellular immunity was a consequence of the atrophy of thymus and thymus-dependent lymphoid tissues as obtained from immunosuppressive chemotherapy.

- 5342 IMMUNOLOGIC STUDIES ON VIRUS-INDUCED MOUSE AND RAT LEUKEMIAS. II. DEMONSTRATION OF A MEMBRANE-BOUND, GROUP SPECIFIC LEUKEMIA ANTIGEN IN GRAFFI AND GROSS LEUKEMIAS. (Ger.) Micheel, B. (Res. Ctr. Molecular Biol. Med., Berlin, West Germany), G. Pasternak and D. Bierwolf. *Acta Biol Med Ger* 28:167-175, 1972.

Experiments with mouse Graffi and Gross leukemias demonstrated that the cell membrane of mouse virus leukemias contains group-specific leukemia antigens, which, however, are not identical with the internal viral antigens. Primary Graffi virus-induced leukemias of the XVII/Bln strain and spontaneous Gross leukemias of the AKR/Bln strain, as well as transplanted rat Graffi leukemias, were used. Immune sera of both rat and mouse Graffi and Gross were used. In immunofluorescent tests, rat Graffi immune sera reacted with mouse Gross leukemia cells as well as with mouse and rat Graffi leukemia cells. No reaction was seen with normal mouse thymus and lymph-node cells. Leukemia-specific Graffi and Gross rat immune sera did not distinguish between Graffi and Gross leukemia cells, in contrast to mouse immune sera. The membrane-associated types and group-specific leukemia antigens must be located adjacent to the antigenic determinants, which are located on one molecule or two adjacent molecules. Another indication of the close association of the determinants is the fact that their antibodies elicit similar effects, such as virus neutralization.

- 5343 IMMUNOLOGIC STUDIES IN VIRUS-INDUCED MOUSE AND RAT LEUKEMIAS. I. DEMONSTRATION OF IDENTICAL ANTIGENS IN GRAFFI VIRUS-INDUCED MOUSE AND RAT LEUKEMIAS. (Ger.) Micheel, B. (Res. Ctr. Molecular Biol. Med., Berlin, West Germany) and G. Pasternak. *Acta Biol Med Ger* 28:157-165, 1972.

Identical virus-induced antigens in Graffi leukemias in the mouse and rat were demonstrated with the aid of serologic methods. The Graffi leukemias were induced by the injection of the XVII/Bln strain into newborn animals, mice receiving 0.1 ml of a 1:10 (G/V) and rats 0.4 ml of a 1:5 (G/V) filtrate mixture. The mouse Graffi immune sera were obtained from adult XVII/Bln mice. Since following absorption of mouse Graffi immune sera with rat Graffi leukemia cells, there was no evidence of Graffi antibodies, it is concluded that even in the membrane of rat leukemia cells both leukemia specific antigens exist. In the immunofluorescent test, rat Graffi

immune sera reacted just as well with mouse as with rat leukemia cells, and likewise neutralized Graffi leukemia virus. The results indicate that these antigens are coded by the viral and not by the cellular genome.

- 5344 PRESENCE OF ANTIBODY AGAINST MOUSE FETAL ANTIGEN IN THE SERA FROM C57BL/6 MICE IMMUNIZED WITH RAUSCHER LEUKEMIA. (E.) Ishimoto, A. (Aichi Cancer Ctr., Nagoya, Japan) and Y. Ito. *Cancer Res* 32(11):2332-2337, 1972.

The presence of a cross-reacting antibody against embryonic cells and Rauscher leukemia cells in sera from the C57BL/6 mice immunized with Rauscher leukemia cells was demonstrated by the indirect immunofluorescent test. Such cross-reacting antigenicity was also found in the SV40-transformed BLSV cells and AKR lymphoma cells. The antibody was completely absorbed with embryonic cells but not with adult spleen cells. Absorption tests showed that this antigen was different from Gross and Friend-Moloney-Rauscher antigens. However, the cross-reacting antibody was not detectable in the sera from 13-month-old mice in which the natural antibody against Gross antigen was clearly demonstrated.

- 5345 INTRACELLULAR AND MEMBRANE IMMUNOFLUORESCENCE INVESTIGATIONS ON CELLS INFECTED WITH HERPESVIRUS SAIMIRI. (E.) Pearson G. (Nat'l. Cancer Inst., Bethesda, Md.), D. Ablashi, T. Orr, H. Rabin and G. Armstrong. *J Nat cancer Inst* 49(5):1417-1424, 1972.

Herpesvirus saimiri (HVS)-induced intracellular and cell membrane antigens were demonstrated in infected owl monkey cells by indirect immunofluorescence methods. Sera from HVS-infected owl monkeys were the source of antibody. The fluorescent reagent was a fluorescein isothiocyanate (FITC)-conjugated caprine antihuman γ -globulin. The effectiveness of the procedure was evaluated on owl-monkey lymphoid cells infected with HVS. Intracellular antigens were detected in infected cells after *in vitro* cultivation but not in uninfected cells or fresh biopsy material from HVS-infected monkeys. These antigens were demonstrated with post-HVS infection sera from 6 owl monkeys but not with sera taken before or within 5 days after HVS infection. HVS-associated membrane antigens were shown in cells productively infected with the virus. The appearance of these antigens coincided with cytopathogenic changes associated with the viral infection. This was particularly evident in an infected owl-monkey kidney culture, where only the rounded cells, not the adherent monolayer, contained both intracellular and membrane antigens. Similar observations were obtained when vero cells, cocultivated with a non-virus-producing marmoset lymphoid cell line, showed cytopathology characteristic of HVS infection. These results demonstrate that membrane antigens are expressed in cells infected with HVS and suggest that their synthesis is a late event in the replicative cycle of this virus.

(5346-5350)

- 5346 DETECTION OF HL-A AND OTHER CELL-SURFACE ANTIGENS ON CULTURED CELLS BY A CYTOTOXIC PLATING INHIBITION TEST. (E.) Takasugi, M. (Sch. Med., U. California, Los Angeles) and P. I. Terasaki. *J Nat Cancer Inst* 49(5):1229-1237, 1972.

A cytotoxic plating inhibition test detected HL-A and other cell-surface antigens on cultured tumor and normal cells. Cultured target cells were typed for HL-A specificities to avoid misinterpretation of HL-A reactions for tumor-associated activity. The validity of the antigens detected was supported by comparisons with lymphocyte typing. When sera from cancer patients were analyzed for HL-A reactivity by being screened against lymphocyte samples from 80 different donors, between 5 and 10% possessed this activity. Aside from these HL-A reactions, a significant degree of cytotoxicity not associated with specific histologic types of tumors was found with sera from cancer patients on cells cultured from tumors and even from normal tissue. Moreover, antigens were detected with sera from normal individuals as well as patients. The demonstration of antigens on cell membranes of cultured cells other than tumor-associated HL-A antigens has implications for interpretations of tests on cultured tumor cells.

- 5347 IMMUNOLOGICAL STUDIES ON VIRAL POLYPEPTIDE SYNTHESIS IN CELLS REPLICATING MURINE SARCOMA-LEUKEMIA VIRUS. (E.) Shanmugam, G. (St. Louis U. Sch. Med., Mo.), G. Vecchio, D. Attardi and M. Green. *J Virol* 10(3):447-455, 1972.

The synthesis of viral polypeptides in the transformed, virus-producing rat cell line 78A1 was studied using antibodies to disrupted murine sarcoma-leukemia virus (MSV[MLV]). When cultures were labeled for 10 min with radioactive amino acids, about 9% of the total labeled proteins was precipitated with antiserum against purified MSV(MLV), and 3 to 4% was precipitated with the same antiserum after it had been absorbed with an extract from uninfected rat cells. The difference is due to the presence in the unabsorbed antiserum of antibodies to cellular proteins that are present in purified virus preparations. Intracellular viral proteins labeled with radioactive amino acids were isolated by immunoprecipitation and analyzed by electrophoresis in sodium dodecyl sulfate-polyacrylamide gels. The mobilities of intracellular viral polypeptides were identical to those of the purified virion. However, labeled polypeptides with electrophoretic mobilities lower than that of the major virion polypeptide, the group-specific antigen of molecular weight 31,000, were present in higher proportion in the total cell extract and in the membrane fraction than in the virion. These polypeptides appeared to be of cellular origin for they were present only in minute amounts in the immunoprecipitates obtained with the absorbed serum. After a 10-min labeling period, radioactive proteins were assembled into extracellular virions rapidly for the first 4 hr followed by a slower rate. More than 2% of the total proteins of the cell labeled in a 10-min pulse were assembled into virions at the completion of a 24-hr chase. The

high-molecular-weight polypeptides with the same mobilities as those detected in the immunoprecipitate of intracellular proteins were found in virions released from cells after a 10-min pulse. A larger proportion of these high-molecular-weight proteins was detected in virions released after short chase periods (30-120 min) than after longer chase periods (6-24 hr). These data suggest that the high-molecular-weight cell-derived polypeptides have a turnover rate higher than that of the major virion polypeptides or are cleaved proteolytically from the virions during long incubation in the culture media.

- 5348 THE POSSIBILITY OF MOLONEY SARCOMA VIRUS UTILIZATION TO INCREASE THE RESISTANCE OF BALB/c MICE AGAINST METHYLCHOLANTHRENE-INDUCED SARCOMA IMPLANTATION. (Uk.) Fedorovska, M. I. (Sci. Res. Inst. Exp. Clin. Onkol., Kiev, USSR), P. P. Verkhatsky, O. P. Vyetkova, L. P. Kaminska, and Yu. O. Umansky. *Mikrobiol Zh* 34(1):59-60, 1972.

The spectrum of Moloney sarcoma resorption-induced immunity was studied in two-month-old BALB/c mice subjected to Moloney sarcoma virus treatment by i.m. inoculation of a 10% Moloney sarcoma cell-free filtrate. Tumor resorption occurred 35-40 days after virus inoculation whereupon the mice were inoculated with 10^5 methylcholanthrene-induced sarcoma cells. A tumor incidence of 66.6% among intact control mice was observed 25 days later, while only 13.3% of the mice with a resorbed Moloney sarcoma history developed neoplasms. Two of these latter mice also had a recurrent Moloney sarcoma. Apparently, resorption of Moloney sarcoma virus-induced tumors promotes a non-specific tumor transplant immunity.

- 5349 NEOANTIGENS AND VIRUS-TUMORS: FINDINGS AND LOCALIZATION OF NEOANTIGENS IN VIRUS-TRANSFORMED FIBROSARCOMA CELLS OF THE GOLDEN HAMSTER. (Ger.) de Vaux St. Cyr, C. (Cancer Res. Inst., Villejuif, France) and G. P. Tilz. *Z Krebsforsch* 77(3):194-201, 1972.

The appearance of neoantigens in fibrosarcoma cells of the Syrian hamster during transformation with SV40 virus is described. Following the immunization with SV40, the following antibodies appeared: agglutinative, those reacting with T-antigen, and those which precipitated with TSV₅Cl₂-cell extracts. Immunoelectrophoretic analyses revealed three precipitation lines: two of a protein nature and one with a high glucose content. These new antigens differed from the T-antigen and transplantation antigens and were localized with the microsomes. The model described may be applied to the study of tumors with respect to antigen content and immunological defense system.

- 5350 TUMOR IMMUNITY AND THE MECHANISM OF POLYINOSINIC-POLYCITIDYLIC ACID INHIBITION OF TUMOR GROWTH. (E.) Kreider, J. W. (Milton S. Hershey Med. Ctr., Pennsylvania St. U., Hershey) and

S. A. Benjamin. *J Nat Cancer Inst* 49(5):1303--1310, 1972.

The hypothesis that polyinosinic-polycytidylic acid (poly I:C) inhibits tumor growth by stimulating tumor immunity was tested by giving varying doses of poly I:C to tumor-bearing hosts (rats with mammary adenocarcinoma or mice with B16 melanoma) treated with horse antirat or antimouse lymphocyte serum (ALS). These animals were immunosuppressed as demonstrated by their inability to reject skin allografts. Both the rat and mouse tumors in immunosuppressed hosts were retarded by poly I:C treatment, although higher doses were required to overcome the ALS-enhanced tumor growth rate. Poly I:C did not restore the ability of ALS-treated mice to reject skin allografts. To determine whether poly I:C could stimulate the immune response to an X-irradiated tumor cell vaccine, mice were pretreated with: poly I:C, X-irradiated B16 melanoma cells either alone or in combination with poly I:C, or nothing. Mice receiving only poly I:C showed no resistance to subsequent challenge with B16 cells, but mice given X-irradiated B16 cells were resistant. Addition of poly I:C treatment to mice receiving X-irradiated cells did not increase resistance. Thus poly I:C does not stimulate the lymphocyte-mediated immune response to tumor cells and can retard tumor growth in immunosuppressed hosts. Immunostimulation can be excluded as a significant component of the mechanism of poly I:C inhibition of tumor growth.

5351 USE OF THE MACROPHAGE MIGRATION INHIBITION TEST TO MONITOR FRACTIONATION OF SOLUBLE ANTIGENS OF CHEMICALLY INDUCED SARCOMAS OF INBRED GUINEA PIGS. (E.) Suter, L. (Albert Einstein Coll. Med., Bronx, N.Y.), B. R. Bloom, E. M. Wadsworth and H. F. Oettgen. *J Immunol* 109(4):766-775, 1972.

Soluble tumor antigen from 3-methylcholanthrene- and 9,10-dimethyl-1,2-benzanthracene-induced sarcomas grafted onto strain 13 guinea pigs was prepared by extraction with isotonic saline followed by ultracentrifugation. Further fractionation by ammonium sulfate precipitation, gel filtration on Sephadex G-150 or Biogel A-5m, and DEAE Sephadex chromatography was performed. Antigenic activity was assayed *in vivo* by skin tests and *in vitro* by the macrophage migration inhibition method. Antigenic activity was not restricted to a single species of molecules as defined by size or charge. The major part of the activity was associated with two fractions, one excluded by Sephadex G-150, and the other included in Sephadex G-150. The behavior of the antigen preparations in isopycnic sucrose gradient centrifugation indicated that they were truly soluble and not membrane associated. The active fractions were nontoxic for the skin and for peritoneal cells and stable under the conditions of the macrophage migration test. Their antigenic activity was specific for each of the two tumors. In terms of the amount of antigen required to give a positive reaction, the migration inhibition assay was more sensitive than the skin tests. The antigen preparations are potentially useful reagents in tests for tumor specific immunity.

5352 RESISTANCE TO FRIEND LEUKEMIA VIRUS IN MICE: EFFECT OF IMMUNOSUPPRESSION. (E.) Stutman, O. (U. Minnesota Med. Sch., Minneapolis) and J.-M. Dupuy. *J Nat Cancer Inst* 49(5):1283-1293, 1972.

Two types of resistance to Friend leukemia virus were demonstrated in 25 inbred mouse strains and sublines immunosuppressed by heterologous anti-lymphocyte serum (ALS). Sensitivity or resistance to two variants of Friend virus was measured by the capacity of each virus to produce macroscopic foci in the spleens of the infected animals. The first type of resistance (relative resistance) was overcome by effective immunosuppression with ALS, but the second type (absolute resistance) was not affected by ALS treatment. The first type of resistance was also overcome by increasing the virus input; the second type was not affected by large doses of virus. The variations were not due to the differential effects of ALS as an immunosuppressant in the mouse strains studied, since ALS was always effective in depressing cellular and humoral immunity. In the sensitive strains, ALS treatment facilitated virus replication. This increase in virus replication was also observed after ALS treatment in the relatively resistant strains. Conversely, only negligible virus replication was detected in the absolutely resistant mouse strains, and this was not modified by ALS treatment.

5353 ATTEMPTED INDUCTION OF TUMOR ANTIGENS IN CARCINOGEN-TREATED CELLS. (E.) Outzen, H. C. (Inst. Cancer Res., Philadelphia, Pa.), E. J. Andrews, M. A. Basombrio, S. Litwin and R. T. Prehn. *J Nat Cancer Inst* 49(5):1295-1302, 1972.

An attempt was made to confirm the hypothesis that tumor-specific antigens (TSTA) might be induced by chemical carcinogens in cells that otherwise remain normal. Skin from BALB/c or (BALB/c X DBA)F₁ mice treated with 3-methylcholanthrene (MCA) or 7,12-dimethylbenz(a)anthracene (DMBA) was grafted onto normal or immunodepressed syngeneic mice. In three experiments, the syngeneic skin grafts from donors treated with either carcinogen exhibited excessive amounts of graft contraction or rejection. Immunodepression by any of three methods did not reduce the amount of graft rejection to a point where immunologic surveillance of nontumorous cells could be postulated as the responsible mechanisms. The cytotoxicity of the carcinogens was the primary cause of the excessive rejection. In only one experiment did the data suggest a small immunologic component. Thus these experiments did not substantiate the hypothesis that TSTA could be induced by chemical oncogens in cells that otherwise remain normal.

5354 DETERMINATION OF C_3 (COMPLEMENT FACTOR 3) IN MALIGNANT LYMPHOMAS, MYELOMA, AND WALDENSTROM'S DISEASE. (Dut.) Meier, E. Ch. (Canton Hosp., Zurich, Switzerland) and P. J. Grob. *Dtsch Med Wochenschr* 97(25):967-971, 1972.

(5355-5358)

β_1A (a component of complement factor C'3) determinations are reported in a group of patients with malignant lymphomas, myeloma and Waldenstrom's disease and analyzed for their diagnostic and prognostic significance. The β_1A determinations were carried out in 144 sera from 71 hospitalized or ambulatory patients. In normal blood donors, this determination had a mean value of 143 ± 35.8 mg/100 ml. The results in Hodgkin's disease in remission were normal; patients in stages I-III showed normal or slightly increased β_1A values; and patients in stage IV showed low values. In chronic lymphatic leukemia, results were abnormally low in the active stage. In all cases of Waldenstrom's disease, very low results were observed, although, patients in remission following successful therapy also showed low β_1A values. A similar picture was seen with osteomyelofibrosis. In myeloma, a wide range of β_1A values was observed; only 8 out of 30 serum values were within normal range, 8 were increased and 16 were low. A wide range of results was also seen in reticulosarcoma. Although the β_1A determination in serum is of some diagnostic value, a normal value does not rule out malignant disease.

5355 STUDIES OF HUMORAL AND CELLULAR IMMUNOLOGIC DEFENSE REACTIONS IN LYMPHOGRANULOMATOSIS.

(Ger.) Patakfalvi, A. (Med. U. Pecs, Hungary), A. Gogl, M. Balazs, K. Simon and Z. Kovacs. *Folia Haematol (Leipz)* 96(1):59-67, 1971.

Patients with lymphogranulomatosis (Lg) were studied over a period of years in an attempt to discover to what extent Lg can cause immunological deficiency. In a group of 35 patients (subdivided into those with Lg for 0-5 yr and those with Lg for 5-15 yr), determinations of antibodies were obtained in 35, immunoglobulins in 25, cutaneous tests in 18, and lymphocyte transformation in 13 patients. In patients with a disease duration of 0-5 years (Group 1), the titer of normal antibodies was identical with that of the controls or very slightly increased. In patients with a disease of longer duration (Group 2), the titer values were significantly decreased; in some of these patients, terminally, no antibodies could be observed. The IgG and IgA values were slightly increased in Group 1, and the IgM was normal, although the individual IgM fractions varied considerably. Group 2 patients revealed a significant decrease in all three immunoglobulins. These patients also manifested fewer positive cutaneous reactions than normal controls. In most cases, the transformation of lymphocytes due to phytohemagglutinin also suffered some damage. The antibodies and immunoglobulins, before and after X-ray and cytostatic treatment, showed no marked changes in nine patients until two or three months after treatment, when the IgG and IgM as well as the titer values for some antibodies increased. Cumulative effects should be considered.

5356 THE INFLUENCE OF HETEROLOGOUS ANTILEUKEMIC RABBIT IMMUNE SERA ON THE GROWTH OF A TRANSPLANTABLE LEUKEMIA OF THE XVII/B1n MOUSE STRAIN.

(Ger.) Pasternak, G. (Res. Ctr. Molecular Biol. Med., Berlin, West Germany). *Arch Geschwulstforsch* 39(1):40-43, 1972.

Contradictory reports on the effects of heterologous immune sera on transplanted leukemias in the mouse led to a study of the chemically induced leukemia LME 8 (with nitrosomethylurea). For the production of rabbit immune sera, mouse cells of the XVII/B1n strain were used with leukemia LME 8, Graffi virus induced myeloid leukemia (Grm), Graffi virus-induced reticular leukemia (Grr), and normal lymphocytes from lymph nodes. Heterologous rabbit immune sera thus produced prevented the growth of 10^4 subcutaneously injected cells of LME 8 leukemia. This therapeutic effect was attributed to antibodies against virus-induced membrane-bound antigens. The existence of a leukemia antigen that is not of viral origin appears unlikely.

5357 APPLICATION OF IMMUNOHISTOCHEMISTRY TO STUDY OF AVIAN LEUKOSIS VIRUS. (E.) Dougherty, R. M. (State U. New York, Upstate Med. Ctr., Syracuse), A. A. Marucci and H. S. Distefano. *J Gen Virol* 15:149-162, 1972.

Chicken embryo fibroblasts were infected with serotype A or serotype B avian leukosis virus (ALV) and treated with chicken or hamster anti-type A or anti-type B virus antisera and chicken or hamster anti-peroxidase. A modified peroxidase-labeled antibody test was used to study virus antigens in infected cells. In reactions with unfixed infected cells and type-specific antisera, antibody reactions were localized at the cell surface and only cells infected with the homologous virus were stained. When ALV-infected cells were fixed before exposure to antisera, virus antigens in cell cytoplasm were stained along with plasmalemma antigens; both surface and cytoplasmic reactions were specific for virus envelope serotype. With both virus strains, cytoplasmic antigen was often concentrated in granules that were sometimes vesicular. Hamster group-specific (gs) antibody reacted strongly with fixed chicken cells infected with type A or type B virus. The distribution of hamster antigen was similar to that seen with chicken antisera. Intracellular gs antigen may have been present in a few cells. Unfixed infected cells did not react with hamster gs antibody. Some chicken antisera with specific reactivities for envelope antigen contained both types A and B gs antigens. These sera reacted with fixed cells infected with either type A or B virus, and stained surface and cytoplasmic antigens.

5358 RADIOIMMUNOASSAY OF MAMMALIAN TYPE C VIRAL PROTEINS. I. SPECIES SPECIFIC REACTIONS OF MURINE AND FELINE VIRUSES. (E.) Scolnick, E. M. (Natl. Cancer Inst., Bethesda, Md.), W. P. Parks and D. M. Livingston. *J Immunol* 109(3):570-577, 1972.

Preparations of Rauscher and Kirsten murine leukemia viruses and Snyder-Theilen and Gardner feline leukemia viruses were subjected to Sephadex G-100 chromatogra-

phy and isoelectric focusing to purify the viral group-specific (gs) antigens. Fractions from G-100 were subjected to polyacrylamide gel electrophoresis. These procedures revealed a viral polypeptide of murine and feline viruses; this polypeptide (VP3(gs)) had a molecular wt of about 30,000 daltons. Polyacrylamide gel electrophoresis analysis of VP3(gs) purified by G-100 chromatography and isoelectric focusing showed that the peptide migrated as a single band in three dissociation systems. The VP3(gs) protein from murine and feline viruses had species-specific antigenic reactivities which were not altered by chemical iodination. By employing limiting concentrations of antibody in a radioimmune precipitation assay, unlabeled murine or feline VP3(gs) antigen could be quantitated by competition with the labeled polypeptide. This double antibody VP3(gs) antigen assay was at least 500 times more sensitive than complement-fixation or immunodiffusion. Anti-VP3(gs) antisera detected anti-murine VP3(gs) antibodies at serum dilutions in excess of 1:25,600. The same sera at a 1:2 dilution reacted by immunodiffusion and had an endpoint titer of 1:64 by complement fixation.

- 5359 ISOLATION OF THE SV40 INDUCED TUMOR ("T") ANTIGEN FROM TRANSFORMED HAMSTER KIDNEY CELLS. (E.) Spira, G. (Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel), M. Popescu, S. Cymbalista, N. Biezunski and N. Goldblum. *Arch Gesamte Virusforsch* 37(2/3):236-242, 1972.

A procedure for the isolation and partial purification of tumor ("T") antigen induced by SV40 virus in transformed hamster kidney cells is described. The method involves differential precipitation with ammonium sulfate, fractionation on a hydroxylapatite column and concentration by ultrafiltration. There is very little loss in activity as measured in total CF units and the degree of purification is about one hundredfold. Analysis of the purified preparation indicates four peaks of CF activity ranging in molecular weight from 70,000-400,000.

- 5360 LYMPHOCYTE BASTOGENESIS TO HUMAN LEUKEMIA CELLS AND THEIR RELATIONSHIP TO SERUM FACTORS, IMMUNOCOMPETENCE, AND PROGNOSIS. (E.) Gutterman, J. U. (U. Texas M.D. Anderson Hosp. Tumor Inst., Houston), E. M. Herish, K. B. McCredie, G. P. Bodey, Sr., V. Rodriguez and E. J. Freireich. *Cancer Res* 32(11):2524-2529, 1972.

Lymphocyte blastogenic studies to autologous leukemia cells were carried out in 35 patients with adult acute leukemia. The effects of serum on this response and correlation with studies of general immunocompetence were studied. Twenty-five of 35 patients had positive blastogenesis. Nine patients with acute myelogenous leukemia had complete or partial abrogation of this response in autologous serum. Five patients had facilitation of the blastogenic response in autologous serum compared to the response in allogenic serum. Patients with acute myelogenous leukemia had a more vigorous

response to their leukemia cells than patients with acute lymphoblastic leukemia. Although studies of general immunocompetence tended to correlate with the *in vitro* response to leukemia cells, only one patient who was unresponsive to autologous leukemia cells was immunoincompetent. A good prognosis was correlated with a vigorous response to leukemia cells, inhibition or facilitation of that response by autologous serum, and a persistently positive blastogenic response in remission.

- 5361 ANTIGENIC DIFFERENCES BETWEEN NORMAL MOUSE EPIDERMIS AND METHYLCHOLANTHRENE-INDUCED SQUAMOUS-CELL CARCINOMAS. (E.) Bhattacharaya, M. (Roswell Park Mem. Inst., Buffalo, N.Y.) and C. Carruthers. *Oncology* 26:1-15, 1972.

Urea- and alkali-extractable proteins were isolated from normal epidermis and methylcholanthrene hyperplasia, papillomas and squamous carcinomas of mice. Antisera against these proteins were prepared in rabbits and the IgG fractions were obtained from sera by DEAE-cellulose chromatography. In immunodiffusion tests with partially and extensively adsorbed IgG, urea-extractable carcinoma proteins and epidermal proteins contained some cross-reacting antigens and some non-cross-reacting antigens. The two types of urea-extracted protein contained antibodies against distinct antigens and traces of antibodies against common antigens not present in other tissues. Some urea- and alkali-extractable antigens were common to both epidermis and carcinomas. Urea-extractable antigens were the most distinctive for epidermis and carcinomas. In general, antigens common to epidermal proteins were different from antigens common to carcinoma proteins. Studies of the fixation of antibodies to tissue sediments showed that anti-epidermal antibodies raised against the epidermal urea-extracted antigens were directed against proteins characteristic of the epidermis, and that anti-carcinoma antibodies were directed against proteins characteristic of the carcinomas. There was no significant *in vivo* localization of ¹²⁵I-labeled antibodies against epidermal and carcinoma urea-extracted protein in spleen, kidney or liver, skin or carcinoma of normal or tumor-bearing mice.

- 5362 ONCOGENIC VIRUS RNA ANTIGEN IN HUMAN GLIAL TUMORS. ITS RELATIONSHIP TO CARCINOEMBRYONIC ANTIGENS. (Fr.) Trouillas, P. (Neurol. Hosp., Lyons, France). *Nouv Presse Med* 1(30):1979-1982, 1972.

The presence of antigen gs3 in tumors and sera of patients with gliomas is described. The anti-FelV Rickard and anti-FSV (feline sarcoma virus) sera precipitate the glioma extracts and reveal the same antigen as the anti-glioma sera. This antigen appears in other species as well as in humans (mouse, cat). Sera which do not precipitate antigen gs3 do not precipitate extracts of fetal brain; those that do precipitate gs3 react with fetal brains, which serves as a means of distinguishing between the gs3 antigen and the carcino-fetal glial antigen. The soluble antigen

(5363-5369)

from fetal intestine and brain and from gliomas constitutes one antigenic complex. In the presence of anti-FeLV Rickard serum, there is a reaction which is identical between the fetal cerebral antigen and the soluble extract of fetal colon. Evidence of gs3 was demonstrated in 20 tumors examined, including 15 glioblastomas and astrocytomas, 2 oligodendrogliomas, 2 ependymomas and 1 mixed glioma. This antigen was also found in the serum of nine patients, four of which were autoimmunized by their own tumor. The molecular identity between an antigen of virus RNA and a fetal antigen implies an identical genome.

5363 S 100 PROTEIN IN EXPERIMENTAL RAT TUMORS OF THE CENTRAL AND PERIPHERAL NERVOUS SYSTEM.

(E.) Wechsler, W. (Max-Planck Inst., Cologne, West Germany), S. E. Pfeiffer, J. A. Swenberg and A. Koestner. *Naturwissenschaften* 59(8):370-371, 1972.

Rat central and peripheral nervous system tumors caused by ethyl- and methyl-nitrosourea were examined for the nervous tissue-specific protein S-100. Central nervous system (CNS) tumors included 16 brain tumors and one spinal cord tumor. All but two of these tumors contained S-100 as detected by a complement fixation assay. Amounts of S-100 in CNS tumors ranged from 0-0.70% of total soluble protein. Twenty-one of 22 peripheral nervous system tumors, originating in trigeminal nerves, spinal roots or peripheral nerves, were S-100-positive. S-100 accounted for an average of 0.23% of total soluble protein in peripheral nervous system tumors.

5364 STUDIES OF IMMUNE RESPONSE TO A YOSHIDA HEPATOMA ASCITES TRANSPLANT IN RATS. (Ger.)

Boehmer, E. von (Max-Planck-Inst. Biochem., Munich, West Germany) and R. Bayer. *Z Krebsforsch* 77:45-56, 1972.

Sprague-Dawley, BD VI, and BDE rats were tested to determine the conditions required for a humoral immune response to Yoshida hepatoma ascites (YA) cells. Before transplantation of the YA cells, these cells were made isologous to the recipient animal through three passages. Under these conditions, tumor growth was produced in BD VI and BDE strains with the i.p. injection of 100,000 cells per animal. Tumor-bearing rats of these strains did not produce antibodies having cytotoxic action at 37 C against autologous or isologous grown ascites cells, if the ascites tumor has been grown through three passages in the corresponding isogenic strain before transplantation. In all three strains, antibodies with a cytotoxic reaction at 37 C occurred if the animals exhibited ascites tumors which had been grown through fewer than three passages in isogenic rats. Under these conditions, the BD VI and Sprague-Dawley rats showed a stronger antibody reaction than BDE rats. With oil-induced peritoneal exudates, as well as with the ascitic fluids, complement was demonstrated in all three strains. BDE rats could be immunized against the hepatoma by repeated injections of formalin-fixed YA cells,

but humoral antibodies against the YA cells could not be demonstrated in immune BDE rats, either by the cytotoxic test at 37 C or with the mixed antiglobulin reaction. Since it was not possible to establish the presence of humoral antibodies in the serum of these rats by the methods described, it is assumed that these particular strains react against YA tumors with a cellular immune response.

5365 DETECTION OF IgG ON THE SURFACE OF LYMPHOCYTES AND SEPARATION OF LYMPHOCYTE POPULATIONS WITH ANTISERA. (Fr.) Zagury, D. (Lab. Electron Microscopy Applied to Biology, Natl. Ctr. Sci. Res., Paris, France), S. Avrameas and Paul Zeitoun. *C R Acad Sci (Paris)* 273(7):719-722, 1971.

The electron microscope was used to detect IgG lymphocytes from the spleen and lymph nodes of non-immunized C57Bl mice. These cells were first incubated with serum from rabbits hyperimmunized with mouse IgG to block free aldehyde groups which might cause nonspecific fixation of peroxidase-labeled antibodies and then incubated with rabbit antibodies for mouse IgG which had been conjugated with peroxidase. The cytoplasmic membrane of about 3/5 of these lymphocytes had a positive reaction for IgG, while about 2/5 had a negative reaction. Incubation of lymphocyte suspensions with equal parts of antithymocyte serum and Eagle's medium resulted in the formation of an agglutinate consisting of cells, which had undergone reaction with the antithymocyte serum and referred to as T-cells, which showed no evidence of IgG, while the suspension consisted of lymphocytes giving a positive reaction for IgG. On the other hand, incubation of serum from rabbits hyperimmunized with mouse IgG with lymphocyte suspension and Eagle's medium also produced an agglutinate, but most of the cells in suspension had membranes which did not appear to contain IgG. In this population of lymphoid cells, plasmocytes were found which had IgG in their ergastoplasm.

The oncogenic potential of artificial heterokaryons was studied. Mouse peritoneal macrophages, spleen lymphocytes, hepatocytes and transplantable kidney cells of mice (C57B1/6) and hamster Rous sarcoma tumors (HRT) and Sendai viruses were used. Heterokaryons were obtained by a modification of Harris's method. The cells were incubated with the virus, allowed to settle and centrifuged. Smears were then made. The heterokaryons obtained were studied with the aid of H^3 -thymidine and by observing synthesis of mouse serum albumin (labeled with fluorescent isothiocyanate) by these cells. The hepatocyte and HRT cell hybrids carried properties common to both parent cells. They were capable of multiplying in the culture and of synthesizing albumin. Heterokaryons of hepatocytes and spleen lymphocytes, of hepatocytes and peritoneal macrophages were not obtained. Heterokaryons of kidney cells and spleen lymphocytes were obtained maximally ($8.0 \pm 2.55\%$ of the kidney cells) when their parent cells were in the ratio of 1:10.

- 5399 RECURRENT HYPERPLASIA, ADENOMATOUS HYPERPLASIA AND INVASIVE CARCINOMA, DIFFUSION AND METASTASIZING, GRADING OF ENDOMETRIUM CARCINOMAS (PATHOLOGICAL ANATOMY). (Ger.) Dallenbach-Hellweg, G. (Fac. Clin. Med., Heidelberg, West Germany). *Schweiz Z Gynaekol Geburtsh* 2(4-6):330-341, 1971.

The development of endometrium carcinomas including adenomatous and glandular-cystic hyperplasias is described. The latter are in response to estrogen, which under certain conditions, causes an increase in mitosis, an increase in volume of the stroma and hyperplasia of glandular epithelium. Before the menopause, progesterone acts as a deterrent in the progression of this hyperplasia. Adenomatous hyperplasia is the first histological sign of an estrogen effect. It develops over several years, usually following the physiological menopause, and only rarely in continuous anovulation. If estrogen levels are diminished, the hyperplasia may regress; otherwise there is a progression toward carcinoma. The transition to an irreversible state can be determined histologically as an adenocarcinoma *in situ*, which precedes the invasive carcinoma. The invasive carcinoma can remain under estrogen influence even if estrogen levels decrease. In the adenomatous hyperplasia there is often an increased level of estrogen and concomitantly, a carcinoma.

- 5400 PROLIFERATION OF THE PARENCHYMA AND STROMA IN PRECANCEROUS HYPERPLASTIC NODULES OF MOUSE MAMMARY GLANDS. (Rus.) Belyaeva, N. N. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow)

and Yu. M. Vasil'ev. *Biul Eksp Biol Med* 72(10):75-77, 1971.

Proliferation of the parenchyma and stroma in various nodules of precancerous mouse mammary glands was studied *in situ*. Hyperplastic nodules of the mammary glands of female C3H mice (9-12 months old) which had received single or multiple (up to 100 times) injections of H^3 -thymidine were prepared for histological examinations. Labeled cells were counted for the parenchyma and stroma. According to the characteristic of the proliferation of the nodules, the following three types were classified: 1) nodules whose index of labeled nuclei of the parenchyma and stroma did not differ from that of other normal acini of the mammary glands; 2) nodules in which the index of labeled nuclei of the parenchyma exceeded that of the normal mammary gland, but that of the stroma did not differ from the normal mammary gland; and 3) nodules in which the index of labeled nuclei of the parenchyma and stroma was higher than that of other normal acini of the same mice. Most of the nodules studied belonged to the 3rd group. The capacity of parenchymal cells to proliferate intensively and the capacity of the cells to induce stromal responses are two different signs of carcinogenesis.

- 5401 EARLY HISTOLOGICAL AND HISTOCHEMICAL CHANGES DURING EXPERIMENTAL PRODUCTION OF LIVER CARCINOMA BY DIETHYLNITROSAMINE. (Ger.) Schmitz-Moormann, P. (Path. Inst. U. Marburg and Bonn, West Germany), P. Gedigk and A. Dharamadhach. *Z Krebsforsch* 77:9-16, 1972.

Metabolic changes in hepatocytes at the outset of experimentally induced carcinogenesis were studied by means of enzymatic histochemical procedures. Seventy-six Wistar rats were given drinking water containing diethylnitrosamine (DNA) as a 0.0075 % solution. There were 24 normal controls. The animals were sacrificed at intervals of 7-10 days, in groups of 3 experimental and 1 control, and the livers examined. Carcinogenesis of the liver, on the basis of histological and histochemical manifestations, revealed two distinct cell changes. In the first phase (up to 62 days), a coarse, succeeded by a fine, vacuolization was associated with glycogen and RNA depletion beginning in the center of the lobules. This process expanded with formation of a venous network. A decrease in activity of all enzymes was seen. During the fine vacuolization stage, this process was reversed for the glycogen, RNA, and enzyme activity. The second phase (63-86 days) islets of glycogen-storing hepatocytes appeared in the center of the lobules. These changed to basophilic cells and later became primary carcinoma cells, observed in the third phase (87-127 days). The basophilic cells increased, whereas the glycogen cells decreased. Some macroscopically demonstrable carcinomas were already evident in this phase. From the 128th day on, all the animals revealed one or more macroscopic carcinomas. Trabecular, solid, tubular, and anaplastic carcinomas differed markedly in enzyme profile. Differences in enzyme activity may be due to further mutations which affect the cell organization and metabolism, a preponderance of one particular strain of carcinoma, or the

presence of a variable regulative potential in the primary carcinoma cells which affects enzyme activity.

- 5402 INFECTIOUS MONONUCLEOSIS PRIOR TO ACUTE LEUKEMIA: A POSSIBLE ROLE FOR THE EPSTEIN-BARR VIRUS. (E.) Levine, P. H. (Natl. Cancer Inst., Bethesda, Md.), D. A. Stevens, P. F. Coccia, L. Dabich and A. Roland. *Cancer* 30(4):875-880, 1972.

Antibody titers to Epstein-Barr virus (EBV) "viral capsid antigen" (VCA) and to EBV-associated "early antigen" (EA) were measured by indirect immunofluorescence in sera of three patients in whom infectious mononucleosis (IM) preceded acute lymphocytic leukemia (ALL). Patients were males aged 19, 12 and 16 yr. In one case, ALL appeared in connection with a recurrence of IM 17 months after a prior diagnosis of IM. In the other two cases, ALL was diagnosed a month after appearance of IM. All three patients had anti-EBV VCA antibodies and two had anti-EBV EA antibodies. Although IM and ALL are likely caused by different viruses, EBV may activate an oncogenic process in a manner similar to that described for murine leukemia.

- 5403 OAT-CELL CARCINOMA OF THE LUNG: CLINICAL AND MORPHOLOGICAL STUDIES IN RELATION TO ITS HISTOGENESIS. (E.) Hattori, S. (Ctr. Adult Dis., Osaka, Japan), M. Matsuda, R. Tateishi, H. Nishihara and T. Horai. *Cancer* 30(4):1014-1024, 1972.

Twenty-four cases of oat-cell carcinoma of the lung and four cases of bronchial carcinoid tumor were studied electron microscopically. Serotonin levels of serum and tissue were determined in all cases, and ACTH was assayed in the tumor tissue of seven cases. Neurosecretory-type granules were usually observed in the tumor cells, and they were found concentrated in the pseudopod-like cytoplasmic processes. Serum and tumor tissue serotonin levels were frequently elevated and seemed to correlate to the number of neurosecretory-type granules in tumor cells. In five out of seven cases of oat-cell carcinoma, ACTH and serotonin were simultaneously detected in the tumor tissue. In 139 cases of other types of lung cancer, these granules were not observed, and neither serotonin level nor ACTH activity was elevated in the tumor. These results strongly suggest that oat-cell carcinoma is a special type of lung tumor producing neurosecretory-type granules and also a highly malignant variant of bronchial carcinoid tumor originating in Kulchitsky-type cells found in bronchial glands.

- 5404 FOREIGN-BODY TUMORIGENESIS IN MICE: ULTRASTRUCTURE OF THE PRENEOPLASTIC TISSUE REACTIONS. (E.) Johnson, K. H. (Coll. Vet. Med., St. Paul, Minn.), H. K. G. Ghobrial, L. C. Buoen, I. Brand and K. G. Brand. *J Nat Cancer Inst* 49(5):1311-1319, 1972.

Plastic films were implanted s.c. in the flanks of CBA/H or CBA/H-T6 mice. The implants with their surface-attached cells and surrounding capsules were excised at predetermined intervals (i.e., 1/2, 4, 6, 7, 8, 9, and 10 months post implantation) prior to the development of sarcomas. A portion of the excised implant-capsule complex from each animal was processed for electron microscopic study. Direct flat-face embedding in Spurr's epoxy resin facilitated ultrastructural analysis of film-induced preneoplastic cell and tissue reactions *in situ*. The same general reaction zones were observed in all specimens, regardless of the duration of implantation. The only cells seen in the film-attached monolayer were dormant-appearing macrophages, which also predominated in the space between the monolayer and capsule. The capsule consisted mainly of parallel planes of fibrocytes or fibroblasts separated by bands of mature collagen, but varying numbers of macrophages, neutrophils, eosinophils, and mast cells were also in some specimens. Blood vessels were always restricted to the outermost area of the capsule (i.e., 70-285 μ from the film surface). It was not determined whether the macrophage population is the source of foreign body-induced sarcomas. However, the morphologic appearance and functional reactivity of macrophages possibly reflect specific microenvironmental changes during preneoplastic development.

- 5409 CHILDHOOD MALIGNANCIES IN CENTRAL INDIA. (E.) Grover, S. (Med. Coll., Nagpur, Maharashtra, India) and U. D. Hardas. *J Nat Cancer Inst* 49(4):959-967, 1972.

Cancer was diagnosed in 220 children under 15 yr (144 boys and 76 girls) treated at a hospital in central India from 1966-1971. There was a high frequency of Hodgkin's disease, chronic leukemia, retinoblastoma, and oropharyngeal carcinoma and a low frequency of neuroblastoma. The high frequency of retinoblastoma could be attributed partially to greater ease of diagnosis of this visible malignancy. The relatively high frequency of oropharyngeal carcinoma apparently represents the childhood counterpart of a well-known adult predisposition to this form of cancer in India. Analysis of data from the other part of the Indian subcontinent shows considerable variation in the frequency of childhood cancer according to cell type. Critical epidemiologic methods are required to incriminate genetic, environmental and other oncogenic factors for the variation in frequency of childhood malignancies in India.

- 5410 ANALYSIS OF VARIATIONS IN THE CELL POPULATION KINETICS WITH TUMOR AGE IN THE L1210 ASCITES TUMOR. (E.) Dombernowsky, P. (Finsen Inst., Copenhagen, Denmark) and N. R. Hartmann. *Cancer Res* 32(11):2452-2458, 1972.

L1210 leukemia cells were passaged in DBA/2 mice by weekly i.p. inoculation of 10^5 cells; the mice were killed at intervals between four and nine days after inoculation, and tumor cell cycle kinetics were measured and analyzed using a computer method based on three alternative mathematical models for cell cycle kinetics. Cell growth in L1210 cells was exponential from four to six days postinoculation and cell doubling time (T_D) was 10.1 hr. T_D increased over time, reaching 25 hr between six and seven days postinoculation and 75 hr by seven to nine days. Growth fractions of 1.0, 0.96 and 0.56, resp., were yielded by the three models for the same tumor ages. Cell cycle time (T_C), calculated from the models, was 13.0, 21.0 and 15.3 hr, resp., five, six and eight days postinoculation. The increase in T_C was probably due to an increase in the mean transit time for all phases of the cell cycle. Cell loss was undetectable in five-day tumors, 0.1%/hr in six-day tumors and 2.5%/hr in eight-day tumors. Computer analysis indicated that mode of cell loss was an age-specific elimination of noncycling cells with post mitotic DNA content.

- 5411 TRENDS IN SOME CANCER MORTALITIES IN NEW ZEALAND. (E.) Milne, R. J. (Wellington Hosp., New Zealand), J. W. Logan and N. E. Logan. *NZ J Med* 75(478):149-152, 1972.

Annual death rates per 100,000 population in New Zealand were calculated for leukemia, malignant lymphoma and multiple myeloma during the period

1950-1968. Death rates for leukemia and malignant lymphoma increased by 35 and 30%, resp., in this period, while death rates from myeloma increased 250%. Patterns of incidence were seen for leukemia and lymphoma deaths; a seasonal variation in mortality rates was evident, with peak rates in summer and fall and low rates in winter.

- 5412 URANIUM MILL TAILINGS AND CANCER MORTALITY IN COLORADO. (E.) Mason, T. J. (Natl. Cancer Inst., Bethesda, Md.), J. Fraumeni, Jr. and F. W. McKay, Jr. *J Nat Cancer Inst* 49(3):661-664, 1972.

County-specific mortality statistics for cancer in Colorado from 1950-1967 were studied to determine if reported excessive mortality from lung cancer and leukemia in the Western Slope counties was associated with residential exposure to γ -radiation from uranium mill tailings. No significant excess in mortality from lung cancer or leukemia in the Western Slope counties was detected. Since 1961 there has been a nonsignificant increase in lung cancer among male residents in the Western Slope, but this probably reflects a diluted rate of occupationally induced cancer among uranium miners. Mortality from malignant neoplasms other than lung cancer and leukemia was significantly greater among Western Slope males, but a relation to radiation exposure appears unlikely. Continued monitoring of the population for radiation effects is needed.

- 5413 U.S. CANCER MORTALITY: NONWHITE PRE-DOMINANCE. (E.) Burbank, F. (Natl. Cancer Inst., Bethesda, Md.) and J. F. Fraumeni, Jr. *J Nat Cancer Inst* 49(3):649-659, 1972.

A study of cancer mortality trends in the United States between 1950-1967 revealed an increasing nonwhite-to-white ratio of age-adjusted death rates. Non-white predominance began in 1950 for females and in 1956 for males. Since 1950 males of both races showed increased cancer mortality, but the increase was more rapid among nonwhites. Death rates among white females have declined, while death rates for nonwhite females have remained stable. Nonwhite predominance in cancer mortality was statistically significant for both sexes with nasal cancer, oral cancer, esophageal and gastric cancer and multiple myeloma. Mortality rates for nonwhites rose more rapidly with age than did rates for whites. These data suggest that nonwhites are more exposed or more vulnerable than are whites to carcinogenic factors.

- 5414 LUNG CANCER IN A STEEL CITY: ITS POSSIBLE RELATION TO FLUORIDE EMISSIONS. (E.) Cecilioni, V. A. (Hamilton Gen. Hosp., Ontario, Canada). *Fluoride* 5(4):172-181, 1972.

Between 1966-1968, 300 deaths from primary lung cancer

occurred in the industrial steel city of Hamilton, Ontario. This represents an annual death rate of 34/100,000 population. A breakdown of the city into zones revealed three distinctly different rates: a high of 65/100,000 in the northeast end of the city close to the steel mills; a low of 12/100,000 in the section farthest from the steel mills and 23/100,000 in the intermediate zone. A marked rise in steel production in Hamilton and a corresponding increase in the use of fluorspar (calcium fluoride) as a fluxing agent occurred during the same period. Thus, increased fluoride emissions from the mills may have contributed to causation of lung cancer. Contamination of vegetation and the atmosphere by fluoride was established. The male:female ratio of lung cancer deaths in the high-mortality areas was 14.7:1. A relationship between cigarette smoking and lung cancer was clearly evident.

5415 A SEQUENTIAL SPACE-TIME CLUSTER ANALYSIS OF CANCER MORTALITY IN THE UNITED STATES: ETIOLOGIC IMPLICATIONS. (E.) Burbank, F. (Natl. Cancer Inst., Bethesda, Md.). *Am J Epidemiol* 95(5):393-417, 1972.

A cluster analysis and a time-trend analysis were performed on cancer mortality figures for the United States from 1950-1967. For males, 33 tumor types fitted into one of five geographic clusters and 15 tumor types remained unclustered. For females, 34 tumor types were clustered and 16 unclustered. Time-trend analysis showed rising and falling incidences of tumor types (reticulum cell sarcoma was found to be the most rapidly rising tumor type). When cancer mortality in each of the five cluster areas was divided into rising and falling categories, it became possible to postulate 11 hypothetical carcinogens associated with the 33 clustering tumor types in men and women. One hypothetical carcinogen was postulated to be the causal agent for reticulum cell sarcoma, lung, hypopharynx, floor of mouth, pancreas and six other cancers with a rising incidence. These cancers clustered in the New England and Great Lakes regions. The carcinogen was postulated to be related to cigarette smoking. Solar radiation and "endocrine factors" were two other actual carcinogenic agents which were provisionally identified among the hypothetical carcinogens. Each hypothetical carcinogen was the cause of more than two diverse tumor types, and each had determined the predominant geographic and temporal distribution of the tumor types with which it was associated.

5416 STOMACH CANCER AMONG JAPANESE IN HAWAII. (E.) Haenzel, W. (Natl. Cancer Inst., Bethesda, Md.), M. Kurihara, M. Segi and R. C. K. Lee. *J Nat Cancer Inst* 49(4):969-988, 1972.

Data on food habits, tobacco use, birthplace and occupation were collected from 220 Hawaiian Japanese with stomach cancer and from 440 matched hospital controls. Relative risks for stomach cancer were determined for migrants (Issei) and Nisei and for

Japanese and Western foods. Issei from prefectures with the highest stomach cancer risks in Japan continued to display an excess risk in Hawaii, but this effect did not persist among their Nisei offspring. Lower risks were suggested for Nisei, but not Issei adhering to Western-style diets. These nativity distinctions are consistent with other studies suggesting that early exposures are critical. Associations of stomach cancer with consumption of specific foods were noted. Elevated risks were described for Issei and Nisei users of pickled vegetables and dried/salted fish, the most frequent consumers having the highest risks. Since similar associations did not appear for raw fish and unprocessed vegetables, suspicion is directed to methods of preparation. Low risks were suggested for several Western vegetables, many of which are eaten raw. The associations for uncooked vegetables appeared independent of those found for pickled vegetables; both persisted after control for other facets of vegetable consumption. Associations for tobacco, liquor, coffee, and milk were observed only in the Issei population. Points of consistency between the Hawaii findings and those assembled in Japan are cited. Experimental evidence bearing on the epidemiologic data for processed fish and vegetables is mentioned.

5417 LEUKEMIAS IN THE CRACOW REGION IN THE YEARS 1961-1968 AND CONTAMINATION OF THE ENVIRONMENT BY PESTICIDES. (E.) Janicki, K. (Med. Acad., Cracow, Poland). *Acta Med Pol* 13(1):49-71, 1972.

An attempt was made to correlate leukemia morbidity with intensity of use of chemical agents for plant protection in the Cracow, Poland, region. Data on leukemia incidence and use of chemical agents in this area between 1961-1968 were subjected to statistical analysis. Results indicated several statistically significant correlation coefficients between rural leukemia morbidity and use of chemicals, especially pesticides, seed dressing and herbicides.

5418 INCIDENCE OF LEUKEMIA AND NONLYMPHATIC TUMORS IN MICE WITH GLOMERULOSCLEROSIS AND ALLIED DISORDERS. (E.) Yuhas, J. M. (Oak Ridge Natl. Lab., Tenn.) and N. K. Clapp. *J Nat Cancer Inst* 48(2):367-373, 1972.

The pathology records of 311 RF female mice that died spontaneously were examined for possible non-random associations among five diseases: severe glomerulosclerosis, polyarteritis, arterial hyalinization, leukemia and nonlymphatic tumors. Significant deviations from expected nonrandom occurrence were observed in only two cases. The incidence of polyarteritis (17 of 311 mice) was four times and that of arterial hyalinization (8 of 311 mice) was eight times that expected ($P < 0.01$). The incidence of leukemia (primarily reticulum cell sarcoma) in each of the four disease combinations involving glomerulosclerosis was reduced to about half that expected from random occurrence. No deviations from expectation

could be demonstrated for the incidence of non-lymphatic tumors in glomerulosclerotic mice or in mice with leukemia. No significant differences were observed between leukemic and nonleukemic mice in terms of the site of the nonlymphatic tumors or the frequency of multiple tumors. It was postulated that the decreased incidence of leukemia in glomerulosclerotic mice may be the result of an immune reaction against the leukemia virus which reduces the incidence of leukemia while producing a glomerulosclerotic response.

5419 THE BASIS FOR A TUMOR EPIDEMIOLOGICAL STUDY ON CARCINOMA OF THE BREAST IN THE GDR. (Ger.)

Bauldauf, K. (Dept. Med., Humboldt U., Berlin, East Germany), S. Möpert and G. Mildner. *Radiobiol-Radiother* 12(6):695-714, 1971.

Data necessary for an epidemiologic study are reviewed. The basis for sample selection is often purely random, each of the factors in the study having an equal probability for selection. A study which encompasses a number of factors (age, sex, place of residence, etc.) may use various methods for the selection of a representative sample: pure chance; chance selection in various categories; selection in clumps (as with territorial sampling); and a selection based on sequential events. In the construction of a questionnaire aimed at establishing, for example the etiology of mammary carcinoma, it is important to select reliable individual contact through a semistandardized interview. The establishment of contact is effected by means of a nonstandard interview to begin with. A questionnaire used in an East German epidemiologic study of breast cancer is reproduced. Women from 55 districts were interviewed over a one-yr period by means of the questionnaire.

5420 EPIDEMIOLOGICAL INVESTIGATIONS OF RETICULUM-CELL-SARCOMA AND LYMPHOCYTOSARCOMA IN THE G.D.R.: REPORT ON 4048 CASES. (Ger.) Wolf, M. (Inst. Cancer Res., Ger. Acad. Sci., Berlin, East Germany), H.-J. Herold, W. Gibel and W. Stanezek. *Arch Geschwulstforsch* 39(3):229-239, 1972.

The incidence, organ distribution and sex-orientation, age effect, geographical distribution and comparison with international standards of occurrence of reticular cell sarcoma (RS) and lymphocyte sarcoma (LS), were obtained in 4048 cases in East Germany. Frequency of RS was 3.5 times that of LS. Occurrence in the lymph-node region was 43.2% for RS and 69.4% for LS, both occurring maximally in this region in comparison with other organs. The sex proneness, for all organ groups (for LS and RS), favors the females. Sex differences in susceptibility to RS shows the epipharynx, small intestine, retroperitoneum, respiratory organs and urinary system to be affected most often in males. Up to age 35, the incidence of both RS and LS is low; the maximum figures occur at age 75, men being more susceptible than women at this age. This long latent period is thought to be connected with cumulative exogenous toxic effects.

5421 CANCER MORTALITY AMONG AMERICAN INDIANS, 1950-67. (E.) Creagan, E. T. (Natl. Cancer Inst., Bethesda, Md.) and J. F. Fraumeni, Jr. *J Nat Cancer Inst* 49(4):959-967, 1972.

Between 1950-1967, 2703 American Indian males and 3194 females were reported to have died from cancer. Gallbladder cancer was the only tumor in which mortality among Indian males and females was significantly higher than that among both white and black males and females in the United States. Other surveys have noted increased susceptibility of Indians to a variety of gallbladder diseases: neoplastic, calculous, and inflammatory. Indian females had a significant excess in mortality from cancers of the thyroid, and the nose and paranasal sinuses. However, Indian mortality from all neoplasms combined was significantly lower than expected, especially among males. Deficits in Indian mortality were statistically significant for many cancer sites, particularly large intestine, rectum, lung, prostate, breast, ovary, bladder, and brain, and for Hodgkin's disease. The favorable cancer mortality reported for Indians may be related to their high frequency of diabetes, since other population groups have exhibited a negative correlation between these disorders. The unusual patterns of cancer mortality among Indians suggest advantages in the use of this population for etiologic studies of cancer.

5422 GEOGRAPHIC CLUSTERING OF BRAIN TUMORS IN KENTUCKY. (E.) Brooks, W. H. (U. Kentucky Med. Sch., Lexington). *Cancer* 30(4):923-926, 1972.

An attempt was made to determine the geographic distribution of 612 brain tumors reported in Kentucky from 1963-1969. A geographic cluster was revealed in the eastern section of the state when the tumors were grouped according to county and adjusted for population. The incidence of all brain tumors within these six counties was 3.37 times that of the remainder of the state; the incidence of gliomas within the area was 4.4 times that expected. Within the counties, 66.1% of cases were located along major tributaries of the Kentucky and Licking Rivers. The possibility of contamination of water with chemical carcinogens is suggested as an environmental factor in the production of primary intracranial neoplasms.

5423 SOME FEATURES OF THE MORBIDITY FROM OVARIAN CARCINOMA IN BULGARIA. (Bul.) Velkov, G. (Sci. Res. Inst. Oncol., Sofia, Bulgaria) and N. Monov. *Akush Ginekol (Sofia)* 10(5):382-386, 1971.

The incidence of ovarian carcinoma among Bulgarian women was studied during the 1953-1957, 1961-1964, and 1965-1968 periods. Average indexes of 3, 6.15, and 7.86/100,000 for each period in chronological sequence indicate an increasing trend and an almost threefold increase during the last period under consideration. While least prevalent among the genital carcinomas during the first period, the incidence of

ovarian cancer exceeded that of uterine corpus carcinoma during the second period and almost reached that of cervical carcinoma during the third period. The lowest incidence in ovarian carcinoma was ascertained in the below 29 yr age group; highest figures were found among the 50-59 yr age group with 9.44, 17.73, and 20.22/100,000 indexes for the three consequently considered periods. The incidence indexes increased from 2.7 to 5.8 and 7.4/100,000 among rural women and from 4.6 to 6.0 and 8.6/100,000 among urban women during the same three periods. Further studies are required to interpret the above findings.

- 5424 ALIMENTARY FACTORS IN THE EPIDEMIOLOGY OF GASTRIC CANCER. (E.) Graham, S. (Dept. Social Preventive Med., St. U. New York, Buffalo), W. Schotz and P. Martino. *Cancer* 30(4): 927-938, 1972.

One hundred and sixty male patients and 68 female patients with gastric cancer were compared with controls as to frequency of consumption of certain types of food and modes of food preparation. To control age and socioeconomic factors, the cancer patients and the controls, who had no neoplastic or gastrointestinal disease, were matched on age, birthplace, and ethnic background. Item-by-item analysis of diet for both sexes showed that patients more frequently ingested potatoes, ate lettuce less often, ate more irregularly, and used cathartics frequently. Because diets typically do not consist of single items of food, scaling techniques were used to distinguish differences between cases and controls in frequency of use of groups of food previously hypothesized to be related to the disease. No differences were observed in: 1. duration of use of the several fats used in frying; 2. frequency of ingestion of the various foods consumed fried, considered separately or together, weighting for the number used and the frequency of each; 3. frequency of eating all meats and fish considered separately or together, and 4. frequency of use of the various alcoholic beverages. There was a rather substantial difference in eating vegetables raw. Control patients ate larger numbers of vegetables raw than cancer patients. Low risk of gastric cancer was associated with ingesting in the uncooked state lettuce, tomatoes, carrots, coleslaw, and red cabbage, and risk declined with increases in the number of these vegetables eaten raw.

- 5425 DATA ON THE INCIDENCE OF LEUKEMIAS IN SOCHI AND TUAPSE (1960-1969). (Rus.) Lebedev, V. N. (Sochi Oncol. Clin., USSR), S. G. Belikova, B. A. Betskii, L. A. Korneeva, Yu. L. Lebedeva, M. I. Moiseenko and R. Kh. Yunicheva. *Probl Gematol Pereliv Krovi* 17(2):30-32, 1972.

A total of 360 cases of hemoblastoses was reported in Sochi and Tuapse for 1960-1969. This corresponds to a mean annual incidence index of 14.11/100,000 population. The mean annual index for male (14.54)

exceeded that (13.74) for female patients. The mean annual index of mortality from hemoblastoses was 10.08/100,000 population. The mortality index for acute leukemia was 3.65/100,000; for chronic leukemia, 3.53; for leukemias with destructive growth, 2.90. The incidence of leukemias in 1960-1969 was 51.7/100,000 for Sochi and 60.1/100,000 for Tuapse.

- 5426 LUNG CANCER AND GASTRO-INTESTINAL CANCER IN MINERAL OIL WORKERS. (E.) Waterhouse, J. A. H. (Reg. Cancer Registry, U. Birmingham, England). *Ann Occup Hyg* 15:43-44, 1972.

Evidence is presented which suggests that mineral oil mist is capable of inducing skin, pulmonary, and upper GI tumors in man. Previous studies had shown that the incidence of epitheliomas of the scrotum was increased in men working in the light engineering works of Birmingham, England, where there was exposure to mineral oils. A review of the records of the Birmingham Regional Cancer Registry for the period 1936 to 1967, which included 228 cases of scrotal epithelioma, has shown that the incidence in these patients of second primary tumors of the skin, respiratory system, and upper digestive tract was 3.34 times that expected.

- 5427 INCIDENCE OF LEUKEMIA IN CHILDREN FROM THE BIALYSTOK PROVINCE AND THE CONTENT OF ABSORBABLE MAGNESIUM IN SOIL AND ITS ACIDITY. (Pol.) Rudobielska, M. (Dept. Pediat., Acad. Med. Bialystok, Poland), J. Kurpios, M. Kaczmarzski and I. Krasowska. *Pediatr Pol* 47(6):695-701, 1972.

- 5430 SEARCH FOR GENETIC INFLUENCES ON NEOPLASTIC TRANSFORMATION AND CHROMOSOMAL STABILITY OF MOUSE CELLS CULTURED IN MEDIUM SUPPLEMENTED WITH HORSE OR FETAL BOVINE SERUM. (E.) Parshad, R. (Nat'l. Cancer Inst., Bethesda, Md.) and K. K. Sanford. *J Nat Cancer Inst* 49(4):1155-1163, 1972.

Embryonic cells from three inbred mice strains differing in incidence of spontaneous tumors and susceptibility to induction of tumors were studied for serum effects on neoplastic transformation and chromosome stability. The three mouse strains were A/HeN, germfree ALBM-2, and I/An. The cells were cultured in chemically defined medium NCTC 135 supplemented with horse or fetal bovine serum. A differential effect of these two sera on spontaneous neoplastic transformation was found in the cell lines from the A and ALBM-2 mouse but not in cells from the I mouse. Cells from all three inbred strains showed the differential serum effect on chromosome stability. Cells in horse serum shifted more rapidly from diploidy and had a higher frequency of abnormal chromosomes than those in fetal bovine serum. Greater karyotypic stability, particularly with respect to structural alterations, was observed in the cultured cells from the germfree ALBM-2 mouse than in any other mouse strain studied.

- 5431 TESTICULAR TUMORS IN CHILDHOOD: REPORT OF 545 CASES. (Ger.) Bachmann, K. D. (Pediat. Clin. Westphalia, Wilhelm U., Münster, West Germany) and H. von Grawert. *Monatsschr Kinderheilkd* 120(1):40-46, 1972.

Three children with testicular tumors (a Leydig cell tumor, a reticular sarcoma, and an embryonal teratoma, resp.) are presented, and an additional 542 cases of childhood testicular tumors reported in the literature are analyzed. Sixty-five percent of the reported tumors originated in the germ cells; of these, the most frequent were embryonal carcinomas (24.6%), followed by differentiated teratomas (16%) and adenocarcinoma (15.8%). Among the testicular tumors that did not originate in the germ cells, 10% were Leydig cell tumors and 5% were Sertoli cell tumors. According to the literature, malignancy is more likely to occur in the undescended testicle, although this has not been proven. Some authors claim that tumor formation is associated with trauma; this again has not been substantiated by factual data. Almost invariably, therapy consists of an orchidectomy. Preoperative irradiation is contraindicated for reasons of loss of valuable time; changes in the histological picture which complicate classification and subsequent therapy; inadvertent radiation of benign tumors; and possible effects on spermiogenesis of the healthy testicle. Postoperative irradiation may be helpful in the palliative effects on metastases. The prognosis is better for children under three yr.

- 5432 LONG-TERM SERUM COPPER STUDIES IN ACUTE LEUKEMIA IN CHILDREN. (E.) Tessmer, C. F. (M. D. Anderson Hosp. Tumor Inst., Houston, Texas),

M. Hrgovcic, F. B. Thomas, J. Wilbur and D. M. Mumford. *Cancer* 30(2):358-365, 1972.

Twenty-five children with acute leukemia were studied for the extent of correlation between serum copper levels (SCL) and bone marrow blast cell counts. "Correlation" implies that the serum copper and the blast percentage are both within or both outside their defined clinically normal ranges. Serum copper showed positive correlation with blast cells in 61% of all paired data. These data were divided into two periods, one consisting of the first 30 days after initial treatment was started and the second, the total period after initial therapy for which adequate paired values were available. In the initial 30-day period, there is complete correlation (100%) between serum copper and bone marrow blast percentages. With more extended intervals up to 266 days, the correlation drops to 57.1%. A 77% correlation was found for SCL and marrow blast percentage in leukemia patients in remission. Among conditions associated with noncorrelation of SCL and marrow blast percentage were neoplastic extramedullary proliferation; viral infections, lymphoma development, and respiratory, ear and other "miscellaneous" infections. It was concluded that abnormal SCL reflected abnormal cellular proliferations.

- 5433 *IN VITRO* TRANSFORMATION OF A NEW CELL LINE FROM CHINESE HAMSTER EMBRYOS: EVOLUTION OF TRANSPLANTABILITY, KARYOTYPE AND CELL SURFACE. (Fr.) Berebbi, M. (Res. Service C.R.A.C.M., Marseille, France), Ph. De Micco and G. Meyer. *C R Acad Sci [D] (Paris)* 274(5):772-775, 1972.

A new line of cells from embryos of Chinese hamsters (*Cricetulus griseus*) was successfully and progressively transformed *in vitro*, as evidenced by changes in morphologic and karyologic features and changes in cell surface properties. The cells were cultured in Eagle medium with 10% bovine fetal serum and 0.25% trypsin. After the 15th passage, the culture seemed to be deteriorating, but at the end of one month the first colonies appeared. The culture was redispersed and thereafter developed normally. Cell agglutinability was tested with Concanavalin A and the results expressed as an agglutinability coefficient (AC) indicating time of latent stage, stage of maximal agglutination and the time required to reach this stage. The AC increased from 1 during the 27th passage to 10 during the 43rd passage in a nonlinear manner. Transplantability of cells from the 20th, 35th, and 45th passages was tested by inoculating 2×10^6 cells into the cheek pouch of cortisone-treated Syrian hamsters. The cells induced tumors in 50% of the cases. Karyologic analysis during the 12th, 32nd, and 42nd passages disclosed evolution of the cell strain toward hyperploidy from 22 to 24 chromosomes. In the 42nd passage, populations with 23, 24 and 25 chromosomes were trisomic for the sixth chromosome.

- 5434 KINETIC STUDIES ON PHOSPHOFRUCTOKINASE FROM EHRlich ASCITES TUMOR CELLS. (E.) Sumi, T. (Fac. Pharm. Sci., Hokkaido U., Sapporo, Japan) and M. Ui. *Biochim Biophys Acta* 276(1):19-30, 1972.

Phosphofructokinase (Fru-6-P) was isolated from Ehrlich ascites tumor cells and observed using a coupled assay system employing various substrates and effectors. Fru-6-P at different concentrations was inhibited by high concentrations of ATP; ATP inhibition decreased as Fru-6-P concentration increased. The binding of ATP to the inhibitor site of Fru-6-P may have been abolished by Fru-6-P at saturating concentrations. The cooperative interactions displayed by this enzyme are completely lost in the presence of a saturating concentration of any of the positive effectors (Pi, AMP, ADP, SO_4^{-2}). The resultant hyperbolic saturation curve for Fru-6-P or ATP shows the same pattern regardless of the kind of effectors used, except for the case of ADP which, besides functioning as a positive effector, is inhibitory competitively with ATP. Cooperative interactions of Fru-6-P were completely lost in the presence of a saturating concentration of any of the effectors. All effectors except ADP failed to interact with Fru-6-P catalytic sites, acting instead to abolish allosteric properties of Fru-6-P.

- 5435 INHIBITION OF GLYCOLYSIS IN ASCITES TUMOR CELLS PREINCUBATED WITH 2-DEOXY-2-FLUORO-D-GLUCOSE. (E.) Coe, E. L. (Northwestern U. Med. Sch., Chicago, Ill.). *Biochim Biophys Acta* 264(2):319-327, 1972.

The effect of 2-deoxy-2-fluoro-D-glucose (2-deoxy-2-F-Glc) on glycolysis of a hyperdiploid strain of Ehrlich ascites carcinoma cells was studied *in vitro*. Cell suspensions were preincubated at room temp. ten to 15 min in buffer with or without 2-deoxy-2-F-Glc. The reaction was initiated by addition of 10 mM glucose. Reactions were terminated five to 30 sec later by acidification with perchloric acid. The neutralized acid extract was analyzed for glycolytic intermediate content by enzymatic and spectrophotometric assay. 2-Deoxy-2-F-Glc metabolism was determined in the same manner except that the preincubation step was omitted. In controls, glucose-6-P and fructose-6-P had already reached their maxima (1.8 and 0.5 $\mu\text{moles/ml}$ cells, resp.) at five sec, and levels declined through the remainder of the incubation period. In cells preincubated with 0.5 mM 2-deoxy-2-F-Glc, both hexose monophosphates reached a maximum more slowly (about ten sec) and declined more slowly. Preincubation with 2-deoxy-2-F-Glc depressed fructose-1,6-diP to about one-third the value of controls (11 $\mu\text{moles/ml}$ cells). Triose phosphate was relatively constant and was not appreciably affected by 2-deoxy-2-F-Glc. The phosphoglyceric acids plus phosphoenol pyruvate level tended to rise gradually in analogue-treated cells, whereas it tended to remain constant (2.5 $\mu\text{moles/ml}$ cells) or decline slightly in controls. Pyruvate levels showed a transient rise in controls and a transient decline in treated cells. The

rates of accumulation of lactate were about the same in control and in treated cells. Calculation of the velocities of glycolytic enzymes from intermediate accumulation rates between five and 15 sec after glucose addition revealed a 20-40% inhibition of hexokinase, phosphoglucose isomerase and fructose-6-P kinase, and a slight stimulation of the remainder of glycolysis, thus indicating a block by 2-deoxy-2-F-Glc at or prior to fructose-6-P-kinase. The effect of 2-deoxy-2-F-Glc on the hexokinase reaction of intact cells was determined by using 2-deoxyglucose as a substrate, since 2-deoxy-glucose is phosphorylated by hexokinase but is not further metabolized. The results showed that 2-deoxy-2-F-Glc caused a 30% inhibition of 2-deoxyglucose consumption at both low and high substrate concentrations, indicating that the hexokinase inhibition by 2-deoxy-2-F-Glc was noncompetitive. The actual inhibitory compound could not be identified.

- 5436 SMALL MOLECULAR WEIGHT RNA COMPONENTS IN EHRlich ASCITES TUMOR CELLS. (E.) Høllung-Larsen, P. (Fac. Med., U. Copenhagen, Denmark) and S. Frederiksen. *Biochim Biophys Acta* 262(3):290-307, 1972.

Nuclear and cytoplasmic preparations from Ehrlich ascites tumor cells were extracted by four methods (hot phenol, cold phenol, triisopropyl-naphthalene sulphonate, or sodium dodecyl sulphate in reticulocyte standard buffer and phenol-chloroform), and the RNA was separated by polyacrylamide gel electrophoresis. The four different extraction procedures yielded patterns of small nuclear RNA (nRNA) components which were essentially identical. Ehrlich ascites cells contained five small nRNA components (L, A, C, D and F) which migrated more slowly than 5S RNA and three components (H_1 , H_2 and H_3) which migrated between 5S RNA and tRNA. Isolation and electrophoretic analysis of small nRNA from purified nucleoli and nucleoplasm, although complicated by the presence of large quantities of heterodisperse RNA, indicated that components C and D were localized in the nucleoplasm and component A in the nucleolus. Comparison of electrophoretic mobilities of ^{32}P -labeled nRNA and rRNA indicated that small nRNA was not of ribosomal origin nor was it formed by degradation of rRNA. Each of the small nRNA components comprised about 0.2 to 0.7% of total cellular RNA. Metabolism of small nRNA components L, A, C, D, H_3 and H_{1+2} was compared with that of 5S RNA, tRNA and rRNA by electrophoretic analysis of mixtures of *in vivo* ^{32}P -labeled RNA and *in vitro* ^3H -labeled RNA. $^3\text{H}/^{32}\text{P}$ ratios of the various components indicated that labeling kinetics of L, A, C, H_3 , tRNA and 5S RNA were not significantly different. H_{1+2} was labeled two to three times faster than small nRNA which in turn was labeled two to three faster than rRNA. Similar dual label experiments indicated that H_{1+2} , H_3 , L, A, C and D were either stable or were not transported from the nucleus to the cytoplasm. *In vivo* labeling with ^3H -methyl methionine showed that A, C, D, H_{1+2} and H_3 were methylated. Ascites cells were preincubated with either 3'-deoxyadenosine (15-30 $\mu\text{g/ml}$, 35 min, 37°C) or actinomycin D (44 $\mu\text{g/ml}$, 10 min, 37°C) followed

by a three hr incubation with ^3H -uridine. These were mixed with cells labeled with ^{32}P for 72 hr *in vivo* to study inhibition of small mRNA synthesis. Actinomycin D inhibited tRNA, H_{1+2} and H_3 less than A, C and D, which were in turn less inhibited than 5S RNA. $3'$ -Deoxyadenosine inhibited tRNA, H_{1+2} , H_3 and 5S RNA to about the same extent, which was greater than the inhibition of A, C and D. Electrophoretic analysis of small mRNA from Ehrlich ascites cells, Yoshida ascites cells and L 5178 Y lymphoblasts showed identical mobilities for all components. L, C, D, 5S and tRNA from HeLa and Ehrlich cell nuclei showed identical migration patterns on polyacrylamide gels. Component A migrated differently and component K, present in HeLa cells, was absent in ascites cells.

- 5437 THE EFFECT OF CANCER ON CELL TURNOVER IN MOUSE ORGANS. (Ger.) Lockner, D. (Inst. Theoret. Alcohol Res., Karolinska Inst., Stockholm, Sweden), U. Ericson and A. Pettersson. *Z Krebsforsch* 77:1-8, 1972.

The cachexia which accompanies the cancer syndrome was studied with respect to cell turnover by determining the incorporation of ^{14}C thymidine into DNA in various mouse organs after inoculation of mice with ELD tumor. At a tumor size of 13% of body wt, total body wt remained unchanged, indicating the occurrence of a relative cachexia. The only significant reduction occurred in the intestinal fat content. The liver and spleen increased in wt, a change that was accompanied by increased DNA synthesis. The DNA turnover of all other organs remained unchanged. Tumor inoculation stimulated a transitory increase of DNA synthesis in kidneys and muscles. The results indicate that cachexia cannot be attributed to reduced cell synthesis or increased cell destruction in the organs examined. An early decrease of label in the spleen and a concomitant increase in the liver, kidney, and muscle may indicate cell migration.

- 5438 MIXED TUMORS OF SALIVARY GLANDS: LONG-TERM FOLLOW-UP. (E.) Krolls, S. O. (Armed Forces Inst. Path., Washington, D.C.) and R. C. Boyers. *Cancer* 30(1):276-281, 1972.

A long-term follow-up study of the behavior of mixed human tumors of salivary gland origin was undertaken to determine the recurrence rate and the histologic pattern associated with recurrence. Complete follow-up information was obtained in 89 of the first 100 cases of mixed salivary gland tumors diagnosed at the Armed Forces Pathological Institute after January 1, 1945. The median age at the time of surgery in this group was 29.5 yr, somewhat younger than the general experience. Seventy-eight of the patients were male and 11 were female. Both the above findings were biased, however, due to the military source of the cases. Seventy-five of the patients were Caucasians, nine were Negroes and one was Oriental (in four cases, race was not stated). There was no difference between white and nonwhite patients concerning the relative incidence of cases with respect to their respective

population sizes. Of the 89 tumors, 74 were located in the parotid gland, 11 in the submandibular gland, and four in minor salivary glands. There were none in the sublingual gland. Thirty-nine of the 89 patients experienced one to five recurrences each, corresponding to a recurrence rate of 43.8%. Most (53.9%) of the patients had only one recurrence. The highest recurrence rate was in the parotid gland, where 50% of the tumors recurred. The high recurrence rate in the series was most probably due to inadequate surgical removal of the primary lesion. Most recurrences occurred within ten yr. Most of the recurrent nodules were composed of a purely myxoid stroma, while a few were highly cellular.

- 5439 CONTENT OF NUCLEIC ACIDS IN SUBCELLULAR STRUCTURES IN NORMAL AND EXPERIMENTAL LEUKEMIA IN MICE. (Rus.) Bala, Yu. M. (Voronezh Med. Inst. USSR) and V. M. Lifshits. *Probl Gematol Pereliv Krovi* 16(12):41-44, 1971.

Quantitative changes in RNA and DNA levels were studied in the subcellular structures of the liver, spleen, tumor tissue, and pure culture of hemocytoblasts of mice with experimental (i.p. inoculated) leukemia. The levels of RNA and DNA were determined spectrophotometrically. The levels of nucleic acids in cell nuclei of the liver and spleen increased in acute reticulosis-hemoblastosis. The DNA levels in cell nuclei of the liver, spleen, tumor tissue increased in proportion to the levels of blast elements in the cells. In other words, the high DNA level in hemoblastic cells is due to the increase in the ploidy of these cells. A cytophotometric study showed that 16.5% of the hemocytoblasts studied were tetraploidy or higher. RNA/DNA ratio in the mitochondria decreased in the liver and spleen of animals with leukemia. The RNA levels in the microsomes of hemocytoblasts and tumor tissue cells were higher than those in the microsomes of the liver and spleen.

- 5440 PROTEIN CONTENT AND BIOLOGICAL ACTIVITY OF RIBOSOMAL PARTICLES OF CELLS FROM KREBS II ASCITES CARCINOMA. (Rus.) Fais, D. A. (Acad. Sci. USSR, Moscow), R. S. Shakulov and E. V. Klyachko. *Biokhimiia* 36(5):1033-1041, 1971.

Chemical composition and biological activity of ribosomes and polyribosomes from Krebs II ascites carcinoma cells, as affected by the detergent used for their isolation, were studied. Treatment of the mitochondrial supernate with a 1% sodium desoxycholate solution or with a mixture consisting of 0.5% sodium desoxycholate and 1% tween 40 produced ribosomes and polyribosomes with 1.57 g/cm³ and 1.50-1.54 g/cm³ buoyant densities in CsCl, resp. The ribosome and polyribosome density variations reflected their protein content. Regardless of their density or protein level, the ribosomes could be dissociated into non-deproteinized 60S and 40S subunits with 1.61 and 1.52 g/cm³ densities, resp. Thus the observed ribosome and polyribosome density variations depended on the presence of proteins that were not constituents of

the isolated 60S and 40S subunits. Recombination of the subunits resulted in ribosomes with a 1.57-1.58 g/cm³ density. Ribosomes and polyribosomes with buoyant densities in CsCl of 1.50-1.54 g/cm³ showed endogenous protein-synthesizing activity and were capable of synthesizing polyphenylalanine in the presence of polyuridines. On the other hand, ribosomes and polyribosomes with 1.57-1.58 g/cm³ density and the subunits were biologically inactive. In these denser ribosomes, protein-synthesizing factors are absent. Sodium desoxycholate-treated ribosomes and recombined subunits accomplish synthesis of polyphenylalanine in presence of polyuridines only by addition of protein fractions obtained by the dissociation of initial sodium desoxycholate-tween-treated ribosomes.

- 5441 ADENYL CYCLASE AND PHOSPHODIESTERASES IN SOMATIC HYBRIDS OF GLIAL CELLS. (Fr.) Benda, P. (Lab. Mol. Biol., Coll. of France, Paris), J. Premont and S. Jard. *C R Acad Sci [D] (Paris)* 275(12):1303-1306, 1972.

The development of the adenylyl cyclase and phosphodiesterase activities of rat glial cells, 3 T 3 fibroblasts and of their hybrids, is described. The results confirm the existence in C 6 glial cells of an adenylyl cyclase sensitive to isoproterenol, and of two phosphodiesterases (PDE I and II). The marked increase in PDE I observed on the seventh day after culture initiation suggests the existence of an induction of this enzymatic activity, similar to the induction observed in fibroblasts under the influence of exogenous 3'-5'-AMP or repeated stimulation with prostaglandins. The hybrid glial cell C 6 x 3 T 3-4 fibroblast behaves in the same way as the parent 3 T 3. Although, on day 3, the hybrid responds with the same intensity as the glial cell to activation by isoproterenol, on days 5 and 7, it behaves as the parent fibroblast.

- 5442 NEONATAL ONCOLOGY. (Fr.) Gubern-Salisachs, L. (Corachan Inst., Barcelona, Spain) and L. Gubern-Pi. *Ann Chir Infant* 12(4):269-284, 1971.

Although at least 60% of the malignant tumors operated on in the first year of life are histologically congenital malformations, such tumors are rarely diagnosed in the neonate. This because the tumors are frequently too small to be apparent and because the association of tumors with neonates is rarely considered. Examples are given of congenital tumors that were diagnosed and treated during the neonatal period and of undiagnosed tumors that led to complications requiring emergency surgery. In some cases, the congenital origin of a tumor was evident only histologically; other undiagnosed tumors might have been suspected from clinical symptoms. Some practical measures are offered: the mother could be X-rayed during pregnancy to determine the possible existence of a tumor; a detailed examination of the placenta could reveal the invasion of a tumor; the neonate should be examined carefully with palpation

of the lumbar fossa, bearing in mind the frequency with which Wilms tumors and adrenal tumors occur in the very young infant. Abdominal and pulmonary tumors may also occur in the neonate. Benign tumors should certainly be extirpated since they do not disappear spontaneously and, if neglected, may cause life-endangering complications. Malignant tumors must also be extirpated; they are not always incurable.

- 5443 ANEMIC STRESS AS A TRIGGER OF MYELOGENOUS LEUKEMIA IN THE UNIRRADIATED RF MOUSE. (E.) Gong, J. K. (Sch. Dent., State U. New York, Buffalo), P. G. Braunschweiger and C. A. Glomski. *Science* 177(4045):274-276, 1972.

Thirty female RF mice, nine wk old, were bled of 50% of total blood volume from the posterior orbital sinus. Hematocrit values, white blood cell counts and percentages of different cell types were monitored for the lifetime of the mice. Mean survival time of the bled mice was 39 wk after bleeding. Ninety-six percent of bled mice developed fatal myelogenous leukemia (ML) by 15 months after venesection. All mice appeared to be naturally prone to ML development, but only 3 of 9 nonbled control animals had died by 65 wk. The anemia resulting from the bleeding was thought to have triggered the overt appearance of ML. The results support the concept of a two-step *de novo* induction of ML.

- 5444 THE MECHANISM OF ACTION OF THE EPIDERMAL GROWTH FACTOR. III. STIMULATION OF THE UPTAKE OF LABELED PRECURSORS INTO RNA, DNA AND PROTEINS BY EGF IN ISOLATED TUMOR CELLS. (E.) Covelli, I. (Inst. Gen. Path., U. Perugia, Italy), R. Mozzi, R. Rossi and L. Frati. *Hormones* 3(3):183-191, 1972.

Epidermal growth factor (EGF) was purified from the submaxillary glands of male mice and used to treat cultures of HeLa and KB (human rhinopharyngeal tumor) cells; ³H-thymidine, ³H-uridine and ¹⁴C-amino acids were also added to mixtures. In HeLa cells, uptake of ³H-thymidine, ³H-uridine and ¹⁴C-amino acids was greater in EGF-treated than in untreated cells, with the increase in ³H-uridine uptake being evident earlier than the increases in the other labeled precursors. Uptake of radioactive precursors in KB cells was also enhanced by EGF. Uptake of ³H-uridine and ¹⁴C-amino acid was lower in EGF-treated KB cells than in EGF-treated HeLa cells.

- 5445 DNA-DEPENDENT DNA POLYMERASES I AND II FROM NORMAL HUMAN-BLOOD LYMPHOCYTES. (E.) Smith, R. G. (Nat'l. Cancer Inst., Bethesda, Md.) and R. C. Gallo. *Proc Nat Acad Sci USA* 69(10):2879-2884, 1972.

Two DNA-dependent DNA polymerases were purified from blood lymphocytes from normal humans and designated DNA polymerases I and II. Both I and II were physicochemically and enzymatically distinct proteins. DNA polymerase I sedimented as two peaks, corresponding to molecular wts of 300,000 and 150,000, while DNA

polymerase II had a molecular wt of about 30,000. II was evidently more basic than I. Unlike leukemic lymphoblast DNA polymerases, neither I nor II transcribed the heteropolymeric regions of 70S avian myeloblastosis virus RNA.

- 5446 DNA-SYNTHESIS TIME OF BONE MARROW CELLS IN HEALTHY AND ASCITES TUMOR-BEARING MICE. (E.) Lala, P. K. (Dept. Anat., McGill U., Montreal, Canada). *Cell Tissue Kinet* 5:79-85, 1972.

DNA-synthesis (S) times of myelocytes and nucleated erythroid cells in the bone marrow of 20 healthy female CF₁ mice and 24 female CF₁ mice bearing advanced Ehrlich ascites tumors were measured with a combined *in vivo-in vitro* double isotope labeling technique. Bone marrow from both femora of animals sacrificed shortly after i.v. injection of ³H-thymidine was placed in homologous plasma at 37 C and immediately incubated with ¹⁴C-thymidine for 15 min. Smears of double-labeled cells and of cells prior to incubation with ¹⁴C-thymidine were autoradiographed. Cells with 3H alone were those that moved out of S *in vivo* during a specified interval, while cells with ¹⁴C(±3H) were those in S at time of sampling. The number of 3H-labeled cells plotted as a fraction against the number of ¹⁴C(±3H) yielded a slope representing the rate of progress of cells out of S. The inverse of this rate was a measure of the S-period. Neither the S-period nor the proliferation rate of myeloiderythroid precursor cells was influenced by the presence of advanced ascites tumor in the hosts. The rate of movement of cells out of S was the same in myelocytes and erythroid cells of both normal and tumor-bearing animals. In contrast, the tumor cells themselves exhibited a marked retardation of the cell cycle, including S-periods, as well as a decline in the fraction of cells actually in the growth cycle. These findings in the aging tumor were probably due to changes in the local ascites environment such as increasing metabolic deficiency or accumulation of toxic products.

- 5447 THE ULTRASTRUCTURE OF HUMAN AND MURINE ASTROCYTES AND OF HUMAN FIBROBLASTS IN CULTURE. (E.) Macintyre, E. H. (Dept. Biol. Sci., U. Denver, Colo.), J. Pontén and A. E. Vatter. *Acta Pathol Microbiol Scand [A]* 80:267-283, 1972.

Morphological studies by electron microscopy and cytochemical studies were undertaken to determine fine structural differences between normal and malignant astrocytes and normal fibroblasts in cell culture. A series of human adult normal astrocytes and malignant astrocytes (including RSV-transformed cells) whose cultural characteristics had previously been reported formed the basis of the study. Also included were matched normal human fetal fibroblasts and astrocytes (from the same fetus) and methylcholanthrene-induced murine malignant astrocytes. Pellets of cells scraped from their culture vessel and sectioned as well as *in situ* preparations were examined. The fibroblasts were the only cells whose external microfibrils were collagenase-sensitive and considered

to be tropocollagen. Both the benign and the malignant astrocytes had intracytoplasmic microfibril bands (gliofibrils) and some had external collagenase-resistant microfibrils. Malignant astrocytes had a much more developed membrane system (used in its widest sense) than normal astrocytes, had many free ribosomes and some had morphologically abnormal mitochondria. Virus was seen only in the murine malignant astrocytes, where it was abundant and of the murine leukemia virus group. Areas interpreted as representing fusion in progress were seen at the surface of some RSV-transformed giant tumor astrocytes. The fine structure of one cell type from an IgG-producing culture from human glioblastoma corresponded with that reported for immunocytes.

- 5448 CYTOGENETIC STUDIES IN CHRONIC LYMPHOCYTIC LEUKAEMIA: I. A STUDY OF 40 PATIENTS. (E.) Woodliff, H. J. (Roy. Perth Hosp., Australia) and G. Cohen. *Med J Aust* 1(19):970-974, 1972.

Cytogenetic studies were performed on blood and bone marrow cells from 40 patients, aged 43-95 yr, with chronic lymphocytic leukemia. Cultures from ten patients showed a normal karyotype with no morphological abnormalities and an aneuploidy of 5% or less. The 30 remaining cases showed increased aneuploidy, though no aneuploid cell lines were seen. Pseudodiploidy was not found in untreated patients, and in no case was any G-group deletion detected. Chromatid breaks and gaps, acentric fragments, rings, dicentric and an atypical chromosome were observed in cells of six treated patients, and two untreated patients showed chromatid breaks. No persistent marker chromosomes were seen.

- 5449 ABDOMINAL TUMORS IN CHILDREN. (Ger.) Rehbein, F. (German Assoc. Pediat. Surg., Bremen, West Germany), L. Nahnsen and H. Kolb. *Langenbecks Arch Chir* 329:118-123, 1971.

Of the abdominal tumors occurring in childhood, neuroblastomas and Wilms tumors are by far the most common. Eighteen cases of neuroblastoma and 32 cases of Wilms tumor treated between 1964-1971 are presented. Some of the tumors were localized; others had infiltrated local areas or metastases to the bones and liver. Treatment of children with neuroblastomas included primary surgery, radio-cobalt therapy and chemotherapy with cyclophosphamide and Vincristin, but these measures were mostly ineffective. The prognosis for abdominal neuroblastomas is very poor with a survival rate between 8-32%. The Wilms tumor results were much better. Of the 32 children treated with surgery, Actinomycin D (plus Vincristin-Endoxan in cases with metastases) and radio-cobalt, 25 survived the five-year period. Surgical methods applied to pulmonary metastases with some measure of success are described. With improvement in treatment, the survival rate has risen from 40 to 60% in these cases.

50 INHIBITORS OF PROTEOLYTIC ENZYMES IN NEOPLASIA. (Pol.) Worowski, K. (Med. Acad., Bialystok, Poland) and R. Farbiszewski. *Wotwory* 21(4):253-259, 1971.

Antienzymes such as antiplasmin, antitrypsin, and total protein levels were determined in: 1) serum of 24 patients (40-60 years old) with different cancers (lungs, stomach, cervix, liver, breast, ovary, uterus, esophagus and sarcoma), 2) pleural and peritoneal exudates of six cancer patients, 3) serum of eight patients 1-2 months after surgical removal of tumor, 4) serum of ten newborn infants, 5) serum of 20 healthy controls. In addition, enzyme activity was determined in serum of Wistar rats after induction of Guerin tumors, in rats with liver necrosis induced by acute or chronic CCl_4 poisoning, in rats with kidney necrosis induced by acute or chronic HgCl_2 poisoning and in healthy rats. Results revealed a statistically significant increase of serum antiplasmin (30% increase in inhibition) in 85% of cancer patients and increase of serum antitrypsin (20%) in 68% of these patients. Serum of rats with Guerin tumor showed a 12% increase in antiplasmin activity. Pleural and peritoneal exudates also showed high enzyme inhibition activity (especially antitrypsin) in spite of twofold lower levels of total protein. Cancer patients enzyme activities returned to normal levels after surgical removal of malignant tumors. Infant activity was only slightly higher than in adults. Serum of rats with liver necrosis showed increased activity of both antienzymes; in rats with kidney necrosis only antiplasmin activity was significantly increased (after chronic poisoning). It is suggested that the elevated levels of these inhibitors are due to increased permeability of tumor cell membranes caused by necrosis, inflammatory foci and circulatory disturbances.

51 DIFFERENCES IN SYNTHESIS AND DEGRADATION OF SERUM PROTEINS IN NORMAL AND HEPATOMA-BEARING ANIMALS. (E.) Ove, P. (U. Pittsburgh Sch. Med., Pa.), M. L. Coetzee, J. Chen and H. P. Norris. *Cancer Res* 32(11):2510-2518, 1972.

The amounts, synthesis, and degradation of several serum proteins were studied in rats bearing Morris hepatoma 7800 and Morris hepatoma 7777. Serum protein compositions in the tumor-bearing animals differed from those in normal rats. There was a slight decrease of albumin and an increase in α -globulin proteins in the circulating blood of the tumor-bearing animals. The increase in α -globulin was larger than could be expected if globulin just compensates for the slight decrease in albumin, resulting in increased protein levels in the hepatoma-bearing animals. Synthesis of serum proteins released into the circulating blood was similar in host and normal rats. α -Globulin proteins in tumor-bearing rats had a decreased rate of breakdown, accounting for the absolute increase of these proteins. The capacity of liver tissue and hepatoma tissue to synthesize albumin differed 11-fold, with the hepatomas showing the lower rate of synthesis. *In vitro* determinations

showed a six- to seven-fold difference. Host liver had the same synthetic capacity as normal liver. Both total protein synthesis and albumin synthesis were inhibited by cycloheximide and puromycin. The albumin synthesized by the hepatomas is apparently not released into the circulating blood to any great extent.

5452 ATYPICAL MITOSES IN HUMAN BRAIN TUMORS (MEDULLOBLASTOMA, GLIOBLASTOMA). (Ger.) Schröder, R. (Path. Inst. U. Cologne, West Germany) and H. Kaess. *Acta Neuropathol (Berl)* 20(2):171-173, 1972.

Atypical mitoses are classified in 40 medulloblastomas, together with their incidence, and compared with previous data on 10 glioblastomas. In the medulloblastomas, irregularly structured mitoses are found more often than in glioblastomas. The distribution of the different types of mitosis is about the same in the two kinds of tumors. Most frequently, chromosome "laggards" occur in the metaphase orientation; others are: "hollow spindles", "colchicine mitoses", multipolar mitoses and chromosome "stickiness". These abnormalities, as with those in other human and experimental tumors, are attributed to necrobiotic processes. The mitotic course in these tumors, as well as in astrocytoma, is quite different from that in mesenchymal tumors.

5453 RELATIVE FREQUENCY OF OVARIAN NEOPLASMS IN CHILDREN AND ADOLESCENTS. (E.) Norris, H. J. (Armed Forces Inst. Path., Washington, D.C.) and R. D. Jensen. *Cancer* 30(3):713-719, 1972.

A series of 353 primary ovarian tumors which occurred in patients less than 20 yr old was studied. Fifty-five percent of the tumors were malignant, 45% benign. Germ cell tumors, the most common category, made up 58% of all ovarian tumors. The proportion of malignant germ cell tumors decreased with increasing age of patients, while the proportion of benign cystic teratomas increased. Embryonal carcinoma and dysgerminoma were more frequent in older patients. Although epithelial tumors represented 19% of ovarian tumors in the under 20 group, none was seen in patients under nine yr old. Neoplasms derived from gonadal stroma accounted for 18% of all ovarian tumors. Adenocarcinomas were very rare (three cases). Only 18 ovarian tumors (5% of total) were present in patients under five yrs.

5454 LEUKOCYTE CHROMOSOME ABNORMALITIES IN ADVANCED NONHEMATOPOIETIC CANCER. (E.) Bridge, M. F. (Mem. Hosp. Cancer Allied Dis., New York, N.Y.) and M. R. Melamed. *Cancer Res* 32(10):2212-2220, 1972.

Karyotypes were done on leukocyte cultures from 25 patients with advanced nonhematopoietic neoplasms. The patients were grouped according to type and amount of drug and/or radiotherapy received, and

chromosome abnormalities were compared in these groups. No chromosome abnormalities were observed in cells of three untreated patients or in cells of six patients given single-drug therapy. Chromosomes were also normal in four patients receiving two or three drugs, but one of three patients receiving six or more drugs had a large number of structural aberrations. Numerical and structural chromosomal changes were most marked in patients treated by radiotherapy, particularly in patients treated by high-voltage irradiation (betatron, cobalt or ^{125}I radiation). The results indicate that chromosomal abnormalities in patients with advanced cancer of nonhematopoietic tissues are due to therapy and not the effects of the neoplasm *per se*.

5455 EFFECTS OF PROTEASE INHIBITORS ON GROWTH OF HAMSTER TUMOR CELLS IN CULTURE. (E.)

Goetz, I. E. (City Hope Med. Ctr., Duarte, Calif.), C. Weinstein and E. Roberts. *Cancer Res* 32(11): 2469-2474, 1972.

Various protease inhibitors were tested for their effects on the growth of transformed hamster fibroblasts in culture. Beef pancreas trypsin inhibitor (BPTI) promoted parallel alignment of hamster tumor cells in culture and increased the adhesiveness of rounded cells. It had a slightly depressing effect on cell proliferation. Soybean inhibitor depressed cell proliferation but had no effect on cell alignment. Egg white inhibitor had no effect on proliferation or cell alignment. The synthetic protease inhibitor *N*- α -tosyl-L-lysine chloromethyl ketone HCl had no effect on cell alignment but depressed cell proliferation. It was toxic in concentrations in excess of 20 μM . BPTI had no effect on cell proliferation or cell interaction of non-tumorigenic hamster embryo cells in culture. The results suggest that some aspects of the morphology and social behavior of the tumor cells studied may be associated with protease activity that can be inhibited by BPTI.

5456 BIOCHEMICAL AND CYTOGENETIC CHARACTERIZATION OF RAT HEPATOMA CELL LINES *IN VITRO*.

(E.) DeLuca, C. (Sch. Dent., St. U. New York, Buffalo), E. J. Massaro and M. M. Cohen. *Cancer Res* 32(11):2435-2440, 1972.

Comparative studies of H4-II-E-C3 cells, from a rat hepatoma and two lines derived from them are described. On the basis of morphology, kinetics of growth, tumorigenicity, and karyotype, the three lines segregated into two distinct groups. All three cell lines were, however, related as evidenced by the presence of certain marker chromosomes. Isozyme measurements could be used to separate these cells into three distinct groups. Quantitative biochemical differences were also discerned among all three lines. These were based on the inducibility of tyrosine aminotransferase with steroid and the activity profile of pyridine-adenine dinucleotide transhydrogenase during the growth cycle. These studies illustrate

the necessity for the use of multiple parameters to characterize evolving cell lines *in vitro*. Furthermore, they suggest the feasibility of using a combination of cytogenetic and biochemical measurements, in conjunction with model systems, for the study of mammalian cell genetics and the question of tumorigenesis.

5457 KARYOMETRICAL AND CYTOCHEMICAL STUDIES OF HARDING-PASSEY MELANOMA AND HORNING-MITCHELY KIDNEY TUMOUR. II. CYTOCHEMISTRY OF NUCLEIC ACIDS AND PROTEINS. (E.) El-Fiky, S. M. (Med. Res. Inst., Alexandria, U.A.R.), T. Y. Fahmy and S. E. Abdo. *Acta Histochem* 42:106-114, 1972.

5458 KARYOMETRICAL AND CYTOCHEMICAL STUDIES OF HARDING-PASSEY MELANOMA AND HORNING-MITCHELY KIDNEY TUMOUR. III. CYTOCHEMISTRY OF SOME HYDROLYTIC ENZYMES. (E.) El-Fiky, S. M. (Med. Res. Inst., Alexandria, U.A.R.), T. Y. Fahmy and S. E. Abdo. *Acta Histochem* 42:115-120, 1972.

5459 KARYOMETRICAL AND CYTOCHEMICAL STUDIES OF HARDING-PASSEY MELANOMA AND HORNING-MITCHELY KIDNEY TUMOUR. I. KARYOMETRICAL STUDIES. (E.) El-Fiky, S. M. (Med. Res. Inst., Alexandria, U.A.R.) and S. E. Abdo. *Acta Histochem* 42:98-105, 1972.

5460 TRIPLE PRIMARY MALIGNANT NEOPLASMS: UTERUS, CAECUM AND STOMACH. (E.) Tosi, P. (Inst. Path. Anatomy U. Siena Civil Hosp. St. Andrea, Massa Marittima, Italy), M. Cintorino, P. Luzi and U. Pavia. *Virchows Arch (Pathol Anat)* 356:89-94, 1972.

5461 CARCINOMA OF THE THYROID IN CHILDREN. (E.) Liechty, R. D. (U. Iowa Coll. Med., Iowa City), S. Safaie-Shirazi and R. T. Soper. *Surg Gynecol Obstet* 134(4):595-599, 1972.

5462 THE CHROMOSOMES OF FIFTY PRIMARY ROUS RAT SARCOMAS. (E.) Mitelman, F. (Inst. Path., U. Lund, Sweden). *Hereditas* 69(2):155-186, 1971.

5463 MESODERMAL MIXED TUMOR OF THE UTERUS. A CYTOLOGIC, HISTOLOGIC, AND ELECTRON MICROSCOPIC CORRELATION. (E.) Boram, L. H. (Mem. Hosp. Cancer Allied Dis., New York, N.Y.), R. A. Erlandson and S. I. Hajdu. *Cancer* 30(5):1295-1306, 1972.

5464 MATERNAL EFFECT ON DEVELOPMENT OF MELANOMA IN HYBRID FISH OF THE GENUS *XIPHOPHORUS*. (E.) Siciliano, M. J. (Dept. Biol., U. Texas M.D. Anderson Hosp. Tumor Inst., Houston) and A. Perlmutter. *J Nat Cancer Inst* 49(2):415-421, 1972.

5465 CANCER OF THE UPPER RESPIRATORY TRACTS OF THE ORAL CAVITY, ESOPHAGUS AND EAR IN PATIENTS WITH TUBERCULOSIS OF THE LUNGS. (Rus.)

oznesenskii, A. N. (Moscow Res. Inst. Tuberc., USSR).
estn Otorinolaringol 33(6):31-34, 1971.

466 PRIMARY OSTEOSARCOMA OF THE HEART. (E.)
 Lowry, W. B. (Med. U. South Carolina,
 Charleston) and E. E. McKee. *Cancer* 30(4):1068-1073,
 1972.

467 LOBULAR CARCINOMA *IN SITU*. SOME ULTRA-
 STRUCTURAL OBSERVATIONS. (E.) Tobon, H.
 (Pittsburgh Sch. Med., Pa.) and H. M. Price.
Cancer 30(4):1082-1091, 1972.

468 FINE STRUCTURE OF BRONCHIOLO-ALVEOLAR CELL
 CARCINOMA. (E.) Kuhn, C. (Washington U.
 Sch. Med., St. Louis, Mo.). *Cancer* 30(4):1107-1118,
 1972.

469 ULTRASTRUCTURE OF THREE CHOROID PLEXUS
 PAPILOMAS. (E.) Carter, L. P. (St. Joseph's
 Hosp. Med. Ctr. Phoenix, Ariz.), J. Beggs and J. D.
 Aggener. *Cancer* 30(4):1130-1136, 1972.

470 CARCINOMA AND ADENOMATOUS POLYPS OF THE
 COLON AND RECTUM IN BIOPSY AND ORGAN TISSUE
 CULTURE. (E.) Kalus, M. (Baylor Coll. Med., Houston,
 Tex.). *Cancer* 30(4):972-982, 1972.

471 LIGHT AND ELECTRON MICROSCOPY OF GIANT-CELL
 GLIOBLASTOMA. (E.) Hadfield, M. G. (Med.
 Coll. Virginia, Richmond) and S. G. Silverberg.
Cancer 30(4):989-996, 1972.

472 METASTATIC MELANOMA WITH BALLOON CELL
 CHANGES. (E.) Ranchod, M. (U. Cape Town
 Med. Sch., South Africa). *Cancer* 30(4):1006-1013,
 1972.

473 CHRONIC MYELOGENOUS LEUKEMIA PRESENTING IN
 BLASTIC CRISIS. (E.) Bornstein, R. S.
 (American Oncologic Hosp., Philadelphia, Pa.), M.
 Nesbit and B. J. Kennedy. *Cancer* 30(4):939-941, 1972.

474 ISOZYME PATTERNS OF BRANCHED-CHAIN AMINO
 ACID TRANSAMINASE IN VARIOUS RAT
 HEPATOMAS. (E.) Ogawa, K. (Sch. Med., Tokushima
 Univ., Japan) and A. Ichihara. *Cancer Res* 32(6):1257-
 1263, 1972.

475 ULTRASTRUCTURAL STUDIES OF A MALIGNANT
 FIBROUS MESOTHELIOMA OF THE PLEURA. (E.)
 Hay, S. (Med. Coll. Virginia, Richmond) and S. G.
 Silverberg. *Arch Pathol* 92(6):449-455, 1971.

476 RESONANT TRANSFER OF ENERGY IN ONCOGENESIS.
 (E.) Baianu, I. (No Affiliation).
J. Univ Bucur (Fiz) 20:57-58, 1971.

5477 BLAST CELL PROLIFERATION IN PERINATAL
 LEUKAEMIA WITH CHROMOSOMAL TRANSLOCATION
 (Bq+; Dq-). (E.) Ponzzone, A. (Inst. Puericulture,
 Turin, Italy), C. De Sanctis, C. Fabris, G. Ciriotti
 and P. Franceschini. *Helv Paediatr Acta* 27:3-13,
 1972.

5478 THE ULTRASTRUCTURE OF MEGAKARYOCYTES IN
 POLYCYTHAEMIA VERA AND CHRONIC GRANULO-
 CYTIC LEUKEMIA. (E.) Lagerlöf, B. (Karolinska
 Hosp., Stockholm, Sweden) and S. Franzen. *Acta
 Pathol Microbiol Scand (A)* 80:71-83, 1972.

5479 BACTERIA IN TUMORS. (E.) Seibert, F. B.
 (VA Ctr., Bay Pines, Florida), F. Yeomans,
 J. A. Baker, R. L. Davis and I. C. Diller. *Trans NY
 Acad Sci* 34(6):504-533, 1972.

5480 MALIGNANCY IN SOLITARY NONFUNCTIONING
 THYROID NODULES. REPORT OF 45 CASES. (E.)
 Nelson, V. R. (Queens Med. Ctr., Honolulu, Hawaii), C.
 Yam and J. J. Ball. *Hawaii Med J* 31(1):24-26, 1972.

5481 CHEMODECTOMATA OF THE GLOMUS LARYNGICUM
 SUPERIOR. (E.) Hooper, R. (Albert Einstein
 Coll. Med., New York, N.Y.). *Laryngoscope* 82(4):686-
 692, 1972.

5482 CARCINOMA *IN SITU* OF THE VAGINA AFTER
 HYSTERECTOMY. (E.) Schiffer, M. A. (Jewish
 Hosp. Med. Ctr. Brooklyn, N.Y.), A. M. Mackles and
 H. J. Greene. *Surg Gynecol Obstet* 134(4):652-654,
 1972.

5483 MELANOMA OF THE VULVA. (E.) Morrow, C. P.
 (Dept. Surg., U. Texas M.D. Anderson Hosp.
 Tumor Inst., Houston) and F. N. Rutledge. *Obstet
 Gynecol* 39(5):745-752, 1972.

5484 SERUM PROTEIN-BOUND FUCOSE IN PATIENTS WITH
 GYNECOLOGIC CANCERS. (E.) Barlow, J. J.
 (Roswell Park Mem. Inst., Buffalo, N.Y.) and P. H.
 Dillard. *Obstet Gynecol* 39(5):727-734, 1972.

5485 ULTRASTRUCTURE OF A WILMS' TUMOUR AND
 MYOGENESIS. (E.) Tremblay, M. (Laval U.
 Hosp., Quebec, Canada). *J Pathol* 105(4):269-277,
 1971.

5486 SURFACE STRUCTURE OF NORMAL AND LEUKAEMIC
 LYMPHOCYTES. I. EFFECT OF MITOGENS. (E.)
 Holt, P. J. L. (Royal Postgrad. Med. Sch., London,
 England), S. G. Pal, D. Catovsky and S. M. Lewis.
Clin Exp Immunol 10(4):555-570, 1972.

5487 TUMOUR IMPLANTATION IN ISCHEMIC, THERMIC
 AND MECHANICAL LESIONS OF THE COLONIC
 MUCOSA. AN EXPERIMENTAL STUDY IN RATS. (E.) Broyn,

T. (Ulleval Hosp., Oslo, Norway). *Acta Chir Scand* 138(2):202-206, 1972.

5488 PANCREATIC-LIKE RIBONUCLEASE ACTIVITY IN THE ASCITES FLUID OF THE NOVIKOFF AND EHRlich TUMORS. (E.) Miron, M. (Hosp. Notre-Dame, Montreal, Quebec, Canada) and R. Morais. *Can J Biochem* 50(7):843-845, 1972.

5489 DECREASE OF SATURATION DENSITY IN CULTURED TUMOR CELLS BY DEXTRAN SULFATE. (E.) Goto, M. (Res. Inst. Tuberculosis, Leprosy Cancer, Tohoku U., Sendai, Japan), Y. Kataoka and H. Sato. *Gann* 63(3):371-374, 1972.

5490 STUDIES ON THE MECHANISM OF GLYCOGEN STORAGE IN ASCITES HEPATOMAS. (E.) Sato, K. (Res. Inst. Tuberculosis, Leprosy, Cancer, Tohoku U., Sendai, Japan) and S. Tsuiki. *Cancer Res* 32:1451-1454, 1972.

5491 PRESERVATION OF ULTRASTRUCTURE IN FREEZE-STORED HUMAN NORMAL AND LEUKAEMIC LYMPHOCYTES. (E.) Hayward, A. F. (Royal Dent. Hosp., London, England) and A. E. R. Thomson. *Acta Haematol* 46(6):338-348, 1971.

5492 TUMOR FORMATION AND PARAPROTEIN PRODUCTION BY MOUSE PLASMACYTOMA CELLS TRANSPLANTED TO HAMSTERS. (E.) Zlotnick, A. (Hadassah U. Hosp. Med. Sch., Jerusalem, Israel) and M. Slavin. *J Immunol* 109(2):388-393, 1972.

5493 COLONY GROWTH OF PERIPHERAL BLOOD CELLS FROM PATIENTS WITH ACUTE LYMPHOCYTIC LEUKEMIA. (E.) Mack, T. (U. Colorado Med. Ctr., Denver), W. A. Robinson and C. P. Holton. *Cancer Res* 32:2054-2057, 1972.

5494 CANCER OF THE CERVICAL OESOPHAGUS. (E.) Stuart, D. W. (Stoke-on-Trent, England). *J Laryngol Otol* 86(4):317-326, 1972.

5495 CHANGE IN ENERGY METABOLISM OF PROLIFERATING GRANULOMA TISSUE IN RESPONSE TO INSULIN AND 2-DEOXYGLUCOSE. (E.) Murakami, K. (Hiroshima U. Sch. Med., Japan) and S. Ishibashi. *Horm Metab Res* 4:77-82, 1972.

5496 ON A RARE GASTRIC NEOPLASIA: CARCINOSARCOMA. (It.) Calabrese, L. (Unif. Hosp. Naples, Italy), A. Dell'Acqua, M. de Micco and A. Santoro. *Rass Int Clin Ter* 52(8):477-486, 1972.

5497 SKIN TUMOURS -- A RETROSPECTIVE STUDY OF TEN YEARS. (E.) Haribhakti, P. B. (Sheth V. S. Gen. Hosp., Ahmedabad, India) and R. C. Mankodi. *Indian Practitioner* 24(6):277-280, 1971.

5498 MALIGNANT LYMPHOMAS ARISING IN PEYER'S PATCHES AND OTHER ORGANS OF UNTREATED NZO/B1 MICE. (E.) Rappaport, H. (Natl. Cancer Res. Lab., U. Otago, Dunedin, New Zealand), M. Bielschowsky, E. F. D'Ath and C. M. Goodall. *Cancer Res* 31:2047-2053, 1971.

5499 RATE OF [³²P]-PHOSPHATE INCORPORATION INTO ACID-SOLUBLE AND rRNA MONONUCLEOTIDES FROM MYELOID TUMOUR (GRAFFI) IN MICE. (E.) Chelibonova-Lorer, H. (Bulgarian Acad. Sci., Sofia), L. Karamoucheva, L. Dolapchiev, V. Zhivkov and M. Jakimov. *Neoplasma* 19(4):299-303, 1972.

5500 CONCENTRATION AND SYNTHESIS OF ACID-SOLUBLE NUCLEOTIDES IN MYELOID TUMOUR (GRAFFI) AND NORMAL MOUSE LIVER. (E.) Chelibonova-Lorer, H. (Bulgarian Acad. Sci., Sofia), V. Zhivkov and M. Jakimov. *Neoplasma* 19(4):293-297, 1972.

5501 THE STUDY OF THE EXCRETION OF ESTROGENS IN PATIENTS WITH BREAST CANCER TREATED WITH ANDROGENS. (E.) Sharoukhova, K. S. (AMS Inst. Exp. Clin. Oncology, Moscow, USSR), N. I. Muraviova, Iu. F. Kurockin and V. V. Vishnyakova. *Neoplasma* 19(4):331-334, 1972.

5502 HEMATOGENOUS DISSEMINATION OF TUMOUR CELLS AND METASTASES FORMATION IN EHRlich ASCITES TUMOUR. (E.) Kiseleva, N. S. (AMS Inst. Exp. Clin. Oncology, Moscow, USSR) and Yu. Ch. Magamadov. *Neoplasma* 19(4):257-275, 1972.

5503 UTILIZATION OF METHIONINE-ACCEPTING tRNA SPECIES FROM *ESCHERICHIA COLI*, ASCITES-TUMOR CELLS, AND YEAST IN HOMOLOGOUS AND HETEROLOGOUS CELL-FREE SYSTEMS. (E.) Drews, J. (Sandoz Res. Inst., Vienna, Austria), H. Grasmuk and R. Weil. *Eur J Biochem* 29(1):119-127, 1972.

5504 TURNOVER OF DEOXYRIBONUCLEIC ACID, HISTONES, AND LYSINE-RICH HISTONE PHOSPHATE IN HEPATOMA TISSUE CULTURE CELLS. (E.) Balhorn, R. (U. Iowa, Iowa City), D. Oliver, P. Hohmann, R. Chalkley and D. Granner. *Biochemistry* 11(21):3915-3921, 1972.

5505 EFFECT OF NEURAMINIC ACID REMOVAL ON THE PROPERTIES OF A VARIANT ALKALINE PHOSPHATASE IN HEPATOMA. (E.) Higashino, K. (Osaka U. Sch. Med., Japan), M. Hashinotsume and Y. Yamamura. *Clin Chim Acta* 40(1):305-307, 1972.

5506 MOLECULAR NATURE OF F₁ HISTONE PHOSPHORYLATION IN CULTURED HEPATOMA CELLS. (E.) Oliver, D. (Coll. Med., U. Iowa, Iowa City), R. Balhorn, D. Granner and R. Chalkley. *Biochemistry* 11(21):3921-3925, 1972.

5507 HUMAN BLOOD MONOCYTES: STIMULATORS OF

- GRANULOCYTE AND MONONUCLEAR COLONY FORMATION
VITRO. (E.) Chervenick, P. A. (U. Pittsburgh Sch.
ed., Pennsylvania) and A. F. LoBuglio. *Science* 178
057):164-166, 1972.
- 08 PAPILLOMATOSIS OF NASAL CAVITY AND PARANASAL
SINUSES (INVERTED PAPILLOMA, SQUAMOUS
PAPILLOMA). A CLINICOPATHOLOGIC STUDY. (E.) Snyder,
N. (Coll. Physicians Surgeons, Columbia U., New
York, N.Y.) and K. H. Perzin. *Cancer* 30(3):668-690,
1972.
- 509 HISTOLOGIC AND ULTRACYTOCHEMICAL STUDIES ON
THYROID MEDULLARY CARCINOMA. DIAGNOSTIC
SIGNIFICANCE OF ARGYROPHIL SECRETORY GRANULES. (E.)
ateishi, R. (Ctr. Adult Dis., Osaka, Japan),
Takahashi and A. Noguchi. *Cancer* 30(3):755-763,
1972.
- 510 MULTIPLE FORMS OF PHOSPHOFRUCTOKINASE IN
RAT TISSUES AND RAT TUMORS. (E.) Kurata, N.
Natl. Cancer Ctr. Res. Inst., Tokyo, Japan), T.
Matsushima and T. Sugimura. *Biochem Biophys Res Commun*
8(3):473-479, 1972.
- 511 AN ABNORMAL OROSOMUCOID IN THE PLASMA OF
PATIENTS WITH NEOPLASTIC DISEASE. (E.)
udman, D. (Emory U. Sch. Med., Atlanta, Ga.),
E. Treadwell, W. R. Vogler, C. H. Howard
and B. Hollins. *Cancer Res* 32:1951-1959, 1972.
- 512 INCREASE OF EXTRAVASCULAR ALBUMIN POOL
AND THE INTRACELLULAR ACCUMULATION OF
VESICLES IN TRANSPLANTED MORRIS HEPATOMA 9121.
(E.) Urban, J. (Biochem. Inst., U. Freiburg,
Germany), J. Kartenbeck, P. Zimmer, J. Timko, R.
esch and G. Schreiber. *Cancer Res* 32:1971-1977,
1972.
- 513 SPECIFIC ESTROGEN-BINDING CAPACITY OF THE
CYTOPLASMIC RECEPTOR IN NORMAL AND NEO-
PLASTIC BREAST TISSUES OF HUMANS. (E.) Wittliff,
L. (U. Rochester Sch. Med. & Dentistry, N.Y.),
Hilf, W. F. Brooks, Jr., E. D. Savlov, T. C.
all and R. A. Orlando. *Cancer Res* 32:1983-1992,
1971.
- 514 VARIATION OF HEPATIC MALIC ENZYME CAPACITY
WITH HEPATOMA SUSCEPTIBILITY IN MICE
OF DIFFERENT GENOTYPES. (E.) Wolff, G. L. (Inst.
Cancer Res., Philadelphia, Pa.) and H. C. Pitot.
Cancer Res 32:1861-1863, 1972.
- 515 THE DEDIFFERENTIATED PATTERN OF ENZYMES
IN LIVERS OF TUMOR-BEARING RATS. (E.)
erzfeld, A. (Harvard Med. Sch., Boston, Mass.) and O.
rengard. *Cancer Res* 32:1826-1832, 1972.
- 516 IMBALANCE IN ORNITHINE METABOLISM IN
HEPATOMAS OF DIFFERENT GROWTH RATES AS
EXPRESSED IN FORMATION OF PUTRESCINE, SPERMIDINE,
AND SPERMINE. (E.) Williams-Ashman, H. G.
(Ben May Lab. Cancer Res., U. Chicago, Ill.),
G. L. Coppoc and G. Weber. *Cancer Res* 32:1924-
1932, 1972.
- 5517 ESTABLISHMENT OF A NEW HUMAN CELL LINE DE-
RIVED FROM NON-MALIGNANT ENDOMETRIUM.
(E.) Arata, T. (Okayama U. Med. Sch., Japan), Y.
Nakazuma, I. Ogawa, Y. Tanaka and K. Hashimoto.
Gann 62(6):549-552, 1971.
- 5518 ESTABLISHMENT AND CHARACTERISTICS OF A
BRAIN-PASSED SUBLINE OF EHRICH CARCINO-
MA. (E.) Hasegawa, Y. (U. Tokyo, Japan), T.
Irikura and D.-I. Mizuno. *Gann* 62(6):545-548, 1971.
- 5519 ANEMIA IN CHICKENS WITH A TRANSPLANTABLE
LYMPHOID TUMOR. (E.) Chandler, F. W.,
Jr. (Coll. Vet. Med., U. Georgia, Athens) and
O. J. Fletcher, Jr. *Cancer Res* 32(10):2160-2166,
1972.
- 5520 CHONDROMYXOID FIBROMA: A CLINICOPATHOLOGIC
STUDY OF 76 CASES. (E.) Rahimi, A.
(Mayo Clin. Mayo Fdn., Rochester, Minn.), J. W.
Beabout, J. C. Ivins and D. C. Dahlin.
Cancer 30(3):726-736, 1972.
- 5521 SMALL CELL (OAT CELL) CARCINOMA OF
MINOR SALIVARY GLAND ORIGIN. (E.) Koss,
L. G. (Mem. Hosp. Cancer Allied Dis., New York, N.Y.),
R. H. Spiro and S. Hajdu. *Cancer* 30(3):737-741,
1972.
- 5522 VERRUCOUS CARCINOMA OF THE LARYNX. A
CLINICAL AND PATHOLOGIC STUDY OF 10
CASES. (E.) Van Nostrand, A. W. P. (Dept.
Path., U. Toronto, Canada) and J. Olofsson. *Cancer*
30(3):691-702, 1972.
- 5523 CONTRIBUTION OF POLYANIONIC CHARACTER OF
DEXTRAN SULFATE TO INHIBITION OF CANCER
METASTASIS. (E.) Suemasu, K. (Natl. Cancer Ctr.
Hosp., Tokyo, Japan), K. Watanabe and S. Ishikawa.
Gann 62(5):331-336, 1971.
- 5524 INHIBITORY EFFECT OF TUMOR-BEARING BLOOD
ON THE INCORPORATION OF LABELED LEUCINE
INTO TISSUE PROTEINS. (E.) Ishikawa, E. (Inst.
Protein Res., Osaka U., Japan), Y. Matsuoka and
M. Suda. *Gann* 62(5):373-380, 1971.
- 5525 CHANGE OF STEMLINE KARYOTYPES IN YOSHIDA
SARCOMA BY APPEARANCE OF PECULIAR MARKER
CHROMOSOMES. (E.) Matsushima, T. (Natl. Inst.
Genetics, Mishima, Japan) and T. H. Yosida. *Gann*
62(5):389-394, 1971.

- 5526 A NEW FLOATING CELL LINE DERIVED FROM HUMAN PULMONARY CARCINOMA OF OAT CELL TYPE. (E.) Oboshi, S. (Natl. Cancer Ctr., Tokyo, Japan), S. Tsugawa, T. Seido, Y. Shimosato, T. Koide and S. Ishikawa. *Gann* 62(6):505-514, 1971.
- 5527 ZINC CONTENT OF FOWL TISSUES AFFECTED WITH AVIAN LEUCOSIS COMPLEX. (E.) Reddy, M. M. (Coll. Vet. Sci., Tirupati, India) and G. A. Sastry. *Curr Sci* 41(11):428-429, 1972.
- 5528 ULTRASTRUCTURAL CHANGES IN THE CAPILLARY BED OF HUMAN PITUITARY TUMORS. (E.) Schechter, J. (Sch. Med., U. Southern Calif., Los Angeles). *Am J Pathol* 67(1):109-126, 1972.
- 5529 COMPARATIVE OLIGONUCLEOTIDE SEQUENCES OF 28S RIBOSOMAL RNA OF NORMAL LIVER AND NOVOKOFF HEPATOMA ASCITES CELLS. (E.) Seeber, S. (Baylor Coll. Med., Houston, Tex.) and H. Busch. *Cancer Res* 31:1888-1894, 1971.
- 5530 EFFECT OF ALBUMIN FRACTION FROM BLOOD OF TUMOR-BEARING RATS ON SERUM PROTEIN PRODUCTION BY ISOLATED PERFUSED NORMAL RAT LIVERS. (E.) Toporek, M. (Jefferson Med. Coll., Philadelphia, Pa.). *Cancer Res* 31:1962-1967, 1971.
- 5531 ALTERATIONS IN MORPHOLOGY AND GROWTH PATTERN IN A TRANSPLANTABLE LEUKEMIA OF RATS. (E.) Zawadzka, Z. Z. (Dept. Natl. Hlth. Welfare, Ottawa, Ontario, Canada) and H. C. Grice. *Cancer Res* 31:1990-1998, 1971.
- 5532 THE REVERSIBLE INHIBITION OF CATALASE ACTIVITY BY NUCLEOTIDES AND ITS POSSIBLE RELATIONSHIP TO MOUSE LIVER CATALASE DEPRESSION INDUCED BY BIOLOGICAL SUBSTANCES. (E.) Hokama, Y. (U. Hawaii Sch. Med., Honolulu) and E. Yanagihara. *Cancer Res* 31:2018-2025, 1971.
- 5533 EFFECT OF RIFAMPICIN AND A DERIVATIVE ON CELLS TRANSFORMED BY ROUS SARCOMA VIRUS. (E.) Vaheri, A. (Dept. Viral Oncology, Public Hlth. Res. Inst. City New York, Inc., N.Y.) and H. Hanafusa. *Cancer Res* 31:2032-2036, 1971.
- 5534 ISOLATION AND ANALYSIS OF GLYCOPEPTIDES FROM MICROSOMES OF AN ASCITES HEPATOMA, AH66. (E.) Funakoshi, I. (Dept. Biol. Chem., Kyoto U., Japan) and I. Yamashina. *J Biochem* 72(2):459-467, 1972.
- 5535 EFFECT OF HOMOLOGOUS RNA POLYMERASE ON THE INCREASE IN CHROMATIN TEMPLATE ACTIVITY OF STIMULATED FIBROBLASTS. (E.) Farber, J. L. (Temple U. Sch. Med., Philadelphia, Pa.), G. Rovera and R. Baserga. *Biochem Biophys Res Commun* 49(2):558-562, 1972.
- 5536 PHOSPHOLIPID-CALCIUM COMPLEXES IN EXPERIMENTAL TUMORS. (E.) Anghileri, L. J. (Tumor Res., Ruhr U., Essen, Germany). *Experienta* 28(9):1086-1087, 1972.
- 5537 DIFFERENTIATION OF NORMAL AND PATHOLOGICAL CELLS BY PYROLYSIS-GLC. (E.) Reiner, E. (Ctr. Dis. Control, Hlth. Services Mental Hlth. Admin., U. S. Dept. HEW, Atlanta, Ga.) and J. J. Hicks. *Chromatographia* 5(9):535-528, 1972.
- 5538 MOLECULAR FORMS OF ENZYMES IN CANCER. (E.) Weinhouse, S. (Temple U. Sch. Med., Philadelphia, Pa.), J. B. Shatton, W. E. Criss and H. P. Morris. *Biochimie* 54(5-6):685-693, 1972.
- 5539 A FACTOR RESPONSIBLE FOR THE METABOLIC DEVIATIONS IN LIVER OF TUMOR-BEARING ANIMALS. (E.) Tanaka, T. (Med. Sch., Osaka U., Japan), S. Yanagi, M. Miyahara, R. Kaku, K. Imamura, K. Taniuchi and M. Suda. *Gann* 63:555-562, 1972.
- 5540 EFFECT OF DIETARY MODIFICATION ON TUMOR GROWTH IN MICE BEARING SARCOMA-180 AND EHRlich CARCINOMA. (E.) Watanabe, M. (Res. Inst. Tuberculosis, Leprosy, Cancer, Tohoku U., Sapporo, Japan) and S. Oka. *Gann* 63:547-554, 1972.
- 5541 NUCLEAR DEOXYRIBONUCLEIC ACID POLYMERASES FROM LANDSCHÜTZ ASCITES-TUMOUR CELLS. (E.) Marshall, V. M. (Dept. Biochem., U. Aberdeen, Marischal Coll., England), J. Bates and H. M. Keir. *Biochem J* 129(2):26p, 1972.
- 5542 HAEMANGIOPERICYTOMA OF THE VULVA WITH METASTASIS TO BONE 14 YEARS LATER. (E.) Reymond, R. D. (Johns Hopkins Med. Inst., Baltimore, Md.), T. A. Hazra, D. W. Edlow and M. S. Bawab. *Br J Radiol* 45(538):765-768, 1972.
- 5543 MICROBODIES IN LEYDIG CELL TUMORS OF RAT TESTIS. (E.) Reddy, J. (U. Kansas Med. Ctr., Kansas City) and D. Svoboda. *J Histochem Cytochem* 20(10):793-803, 1972.
- 5544 AN ELECTROGENIC SODIUM PUMP AS A POSSIBLE FACTOR LEADING TO THE CONCENTRATION OF AMINO ACIDS BY MOUSE ASCITES-TUMOUR CELLS WITH REVERSED SODIUM ION CONCENTRATION GRADIENTS. (E.) Gibb, L. E. (Dept. Biochem., U. Manchester Inst. Sci. Tech., England) and A. A. Eddy. *Biochem J* 129(4):979-981, 1972.
- 5545 RNA BOUND TO NASCENT DNA IN EHRlich ASCITES TUMOR CELLS. (E.) Sato, S. (Inst. Med. Sci., U. Tokyo, Japan), S. Ariake, M. Saito and T. Sugimura. *Biochem Biophys Res Commun* 49(3):827-834, 1972.

- 5637 SPECIFICITIES OF tRNA METHYLASES FROM
MOUSE LIVER AND PLASMOCYTOMA. (E.)
Lau, F. (Inst. Molecular Biol., U. Paris, France),
J. Garbit and J.-M. Dubert. *Biochim Biophys Acta*
277(1):80-86, 1972.
- 5638 BINDING OF ESTRADIOL-17 β TO HUMAN CANCER
TISSUE OF THE FEMALE GENITAL TRACT.
(E.) Terenius, L. (Dept. Pharmacol., Radiotherap.,
& Gynecol., U. Uppsala, Sweden), A. Lindell and
B. H. Persson. *Cancer Res* 31:1895-1898, 1971.
- 5639 POLYMORPHISM OF ALDOLASE IN HENS WITH
LEUKOSIS. (E.) Hadarag, E. (Fac.
Vet. Med., Dept. Biochem., Bucharest, Romania) and
I. Bercea. *Rev Roum Biochim* 9(2):135-142, 1972.
- 5640 RESPIRATORY ACTIVITY OF MITOCHONDRIA
ISOLATED FROM A TRANSPLANTABLE ISLET-CELL
TUMOR AND FROM THE LIVER OF TUMOR-BEARING HAMSTERS.
(E.) Gross, M. D. (Sinai Hosp., Detroit, Mich.),
A. J. Whitty and P. P. Foa. *Cancer Res* 32:1978-
1982, 1971.
- 5641 CARBAMYL PHOSPHATE HYDROLYSIS IN RAT
TISSUES AND TUMORS BY AN ALKALINE
PHOSPHATASE. (E.) Herzfeld, A. (Harvard Med.
Sch., Boston, Mass.) and W. E. Knox. *Cancer Res*
32:1837-1841, 1972.
- 5642 CANCER OF THE NASAL CAVITY AND PARANASAL
SINUSES. (E.) Lewis, J. S. (New York, N.Y.)
and E. B. Castro. *J Laryngol Otol* 86(3):255-262, 1972.
- 5643 RHABDOMYOSARCOMATOUS DIFFERENTIATION IN
MALIGNANT INTRAOCULAR MEDULLOEPITHELIOMAS.
(E.) Zimmerman, L. E. (Armed Forces Inst. Path.,
Washington, D.C.), R. L. Font and S. R. Andersen.
Cancer 30(3):817-835, 1972.
- 5644 CYTOPLASMIC AND NUCLEAR GROWTH DURING THE
PROLIFERATION OF EHRLICH ASCITES TUMOUR
CELLS IN MICE. (E.) Andersson, G. K. A. (Inst.
Zoophysiology, U. Lund, Sweden) and I. P. S. Agrell.
Virchows Arch (Zellpathol) 11:1-10, 1972.
- 5645 TISSUE CULTURE IN TROPHOBLASTIC NEOPLASIA.
(E.) Notake, Y. (Keio U., Tokyo, Japan).
Asian Med J 15(2):5-6, 1972.
- 5646 A STUDY OF THE PATHOLOGY OF THYROID CANCER,
1930-1960. (E.) Lieberman, P. H. (Mem.
Hosp., New York, N.Y.), F. W. Foote, Jr. and
D. Schottenfeld. *Clin Bull* 2(1):7-12, 1972.
- 5647 MAST CELLS IN EPITHELIOMA OF THE LARYNX.
(It.) Bandini, A. (Otorhinolaryngol.
Clin. U. Siena, Italy) and G. Stocchi. *Boll Mal*
Orecch Gola Naso 87(5):400-404, 1969.
- 5648 HORMONAL FACTORS IN THE FORMATION OF
UTERINE MYOMA. (Tur.) Yavuz, H. (Sch.
Med. Women's Hosp., Ankara, Turkey). *Tip Fak Mecm*
24(5):952-962, 1971.
- 5649 ELECTRON MICROSCOPY OF ADAMANTINOMA OF
THE LONG BONES. (Sp.) Schajowicz, F.
(Italian Hosp., Buenos Aires, Argentina), R. L.
Cabrini and R. J. Simes. *Rev Ortop Traumatol*
Lantino-Amer 16(3):185-194, 1971.

- 5650 SARCOMA OF THE PROSTATE GLAND. (E.) Smith, B. H. (Armed Forces Inst. Path., Washington, D.C.) and L. P. Dehner. *Am J Clin Pathol* 58(1):43-50, 1972.
- 5651 STIMULATION BY RETICULOCYTE INITIATION FACTORS OF PROTEIN SYNTHESIS IN A CELL-FREE SYSTEM FROM KREBS II ASCITES CELLS. (E.) Mathews, M. B. (Med. Res. Council Lab. Molecular Biol., Cambridge, England), I. B. Pragnell, M. Osborn and H. R. V. Arnstein. *Biochim Biophys Acta* 278(1):113-123, 1972.
- 5652 PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA-LIKE RED CELL ABNORMALITY IN PATIENT WITH LYMPHOPROLIFERATIVE DISEASE. (E.) Hill, R. S. (Royal Postgrad. Med. Sch., London, England), D. Catovsky and S. M. Lewis. *Br Med J* 4(5841):649-650, 1972.
- 5653 LYMPHOCYTOTOXINS IN LEUKAEMIA. (E.) Dickson, A. (U. Coll. Hosp. Med. Sch., London, England). *Br Med J* 4(5834):209-211, 1972.

- 5665 ACQUIRED HYPERTRICHOSIS LANUGINOSA AND MALIGNANCY. A CLINICAL REVIEW AND HISTOPATHOLOGIC EVALUATION WITH SPECIAL ATTENTION TO THE "MANTLE" HAIR OF PINKUS. (E.) Hegedus, S. I. (Marshfield Clin., Wis.) and W. F. Schorr. *Arch Dermatol* 106(1):84-88, 1972.
- 5666 FATALITIES DURING REMISSION OF CHILDHOOD LEUKEMIA. (E.) Simone, J. V. (St. Jude Children's Res. Hosp., Memphis, Tenn.), E. Holland and W. Johnson. *Blood* 39(6):759-769, 1972.
- 5667 CELLULAR DIFFERENTIATION IN A MURINE MYELOMONOCYTIC LEUKEMIA. (E.) Cline, M. J. (Royal Melbourne Hosp. Victoria, Australia) and D. Metcalf. *Blood* 39(6):771-777, 1972.
- 5668 ACQUIRED LIPIDOSIS: GAUCHER-LIKE CELLS AND "BLUE CELLS" IN CHRONIC GRANULOCYTIC LEUKEMIA. (E.) Dosik, H. (Jewish Hosp. Med. Ctr., New York, N.Y.), F. Rosner and A. Sawitsky. *Semin Hematol* 9(3):309-316, 1972.
- 5669 *IN VITRO* EFFECT OF EPIDERMAL GROWTH FACTOR ON FREE NUCLEOTIDES AND AMINOACIDS TURNOVER IN THE TUMOR CELLS. (E.) Frati, L. (Inst. Gen. Path., U. Perugia, Italy), R. Mozzi, R. Rossi

and I. Covelli. *Ann Ital Dermatol Clin Sper* 25(2): 179-183, 1971.

5670 HEXOKINASE ISOENZYMES OCCURRING IN MALIGNANT HUMAN TUMOR TISSUES. (Rus.)

Meysakh, S. A. (Inst. Exp. Med., USSR Acad. Med. Sci., Leningrad), N. K. Monakhov and A. L. Shvartsman. *Dokl Akad Nauk SSSR* 206(3):743-746, 1972.

5671 MITOCHONDRIAL AND MICROSOMAL CARDIOLIPINS OF JENSEN'S SARCOMA. (Rus.) Dyatlovitskaya,

L. V. (M. M. Shemyakin Inst. Natrl. Comp. Chem. Moscow, USSR), N. P. Gor'kova, B. D. Malere, N. G. Timofeyeva and L. D. Bergel'son. *Dokl Akad Nauk SSSR* 206(3):737-739, 1972.

5672 CHROMOSOMAL ANOMALIES IN "AGED" PS MICE. DISCUSSIONS ON THE ROLE OF AMYLOSE. (Fr.)

Chabanas, A. (Nuclear Stud. Ctr. Grenoble, France) and C. Mouriquand. *C R Acad [D] (Paris)* 275(6): 719-794, 1972.

5673 HISTOCHEMICAL ENZYME STUDIES RELATED TO INVASIVE TUMOR GROWTH. (Ger.) Hecker,

D. (Charite Tumor Clin. Humboldt U. Berlin, Germany). *Acta Histochem* 43:132-152, 1972.

5674 METASTASIS OF THE PENILE CANCER TO THE SKIN OF THUMB - A STUDY ON METASTASIS

OF THE PENILE CANCER. (Jap.) Miyakawa, M. (Kyoto City Hosp., Japan), M. Itoh, H. Ueyama and M. Kuze. *Acta Urol Jap* 18(2):88-96, 1972.

5675 DEPENDENCE OF FIBRINOLYTIC ACTIVITY ON BLOOD LEUKOCYTIC COUNT IN LEUKEMIA.

(Rus.) Krasik, Ya. D. (Chita Med. Inst. USSR) and B. I. Kuznik. *Probl Gemat* 17(4):41-44, 1972.

5676 MULTIPLE MALIGNANT TUMORS. (Ger.)

Hegglin, J. (Waid City Hosp. Zürich, Switzerland) and K. Lindenberg. *Helv Chir Acta* 39:271-277, 1972.

5677 MALIGNANT MELANOMA -- FINDINGS ON THE FALCK HILLARP'S FLUORESCENT TECHNIQUE. (Jap.)

Morishima, T. (Nihon U. Sch. Med., Tokyo, Japan), Y. Ishikawa and M. Endo. *Jap J Clin Dermat* 25(1):51-56, 1971.

5678 ANGIOKERATOMA CIRCUMSCRIPTUM NAEVIFORME.

(Jap.) Tsuji, T. (Osaka City U. Sch. Med., Japan), H. Sakurane and T. Yamamoto. *Jap J Clin Dermatol* 25(1):59-66, 1971.

5679 LACTIC DEHYDROGENASE ACTIVITY IN SERUM AND TISSUE OF CARCINOMA OF THE ENDOMETRIUM.

(Cz.) Laurova, L. (Dept. Gen. Med. Charles U. Prague, Czechoslovakia), J. Cizkova, A. Jandova and V. Skoda. *Sborn Lek* 74(6):188-191, 1972.

5680 CONTRIBUTION TO THE STUDY OF CYSTOSARCOMA

PHYLLOIDES. (Sp.) Capdevila-Torra, J. (Fac. Med., U. Barcelona, Spain), L. Fernandez-Cruz and J. Vila. *Med Clin* 58(1):6-14, 1972.

5681 AUTORADIOGRAPHIC, GENETIC, AND ELECTRON MICROSCOPIC STUDIES OF ENDOMETRIAL ADENOCARCINOMA. (Ger.) Bonilla-Musoles, F. (Women's

Clin. U. Valencia, Spain) and R. Ferres. *Schweiz Z Gynaek* 2(4-6):373-384, 1971.

5682 CONSIDERATIONS ON THE SO-CALLED BIZARRE LEIOMYOMA OF THE MARTIN-STOUT TYPE. WITH

REFERENCE TO A RARE, VULVAR SITE. (It.) Fiumara, A. (Inst. Path. Anat. Histol., U. Catania, Italy), G. Grasso, G. Nuciforo and C. Pellegrino. *Riv Anat Pat Oncol* 36(5-6-7-8):223-253, 1970.

5683 ISOLATION OF A CONTINUOUS EPITHELIOID CELL LINE, HBT-3, FROM A HUMAN BREAST

CARCINOMA. (E.) Bassin, R. H. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.), E. J. Plata, B. I. Gerwin, C. F. Mattern, D. K. Haapala and E. W. Chu. *Proc Soc Exp Biol Med* 141(2):673-680, 1972.

5684 PRIMARY MALIGNANT LYMPHOMAS OF THE DIGESTIVE TRACT. (Fr.) Tabbara, W. S. (French

Sch. Med. Beirut, Lebanon). *Arch Anat Pathol* 20(2):117-129, 1972.

5685 EXTRAMAMMARY PAGET'S DISEASE. ENZYME HISTOCHEMICAL AND ELECTRON MICROSCOPIC

STUDY. (E.) Belcher, R. W. (Cleveland Metropolitan Gen. Hosp., Ohio). *Arch Pathol* 94(1):59-64, 1972.

5686 NATURALLY OCCURRING MEDULLARY THYROID CARCINOMA IN THE RAT. (E.) Boorman,

G. A. (Inst. Exp. Gerontology TNO, Rijswijk, Netherlands), M. J. van Noord and C. F. Hollander. *Arch Pathol* 94(1):35-41, 1972.

5687 EPITHELIAL TUMORS OF THE OVARY. OCCURRENCE IN CHILDREN AND ADOLESCENTS LESS THAN 20

YEARS OF AGE. (E.) Jensen, R. D. (Armed Forces Inst. Path., Washington, D.C.) and H. J. Norris. *Arch Pathol* 94(1):29-34, 1972.

5688 CLONAL DIFFERENCES IN GLUTAMINE SYNTHETASE ACTIVITY OF HEPATOMA CELLS. EFFECTS OF

GLUTAMINE AND DEXAMETHASONE. (E.) Kulka, R. G. (Hebrew U. Jerusalem, Israel), G. M. Tomkins and R. B. Crook. *J Cell Biol* 54:175-179, 1972.

- 5689 HYPOGLYCAEMIA ASSOCIATED WITH PRIMARY HEPATOMA. (E.) Hagan, M. (Korle-Bu Hosp., Ghana) and J. H. Asafu-Adjaye. *Ghana Med J* 11(1):88-89, 1972.
- 5690 MALE HORMONE PRODUCING TUMOUR (ARRHENOBLASTOMA) IN A YOUNG WOMAN. (E.) Ampofo, D. A. (U. Ghana Med. Sch.), E. C. Christian and J. B. Wilson. *Ghana Med J* 11(1):84-88, 1972.

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain three-hundred-fifty abstracts and three-hundred-fifty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume X covers the scientific literature published from July 1971 through Dec 1972. A cumulative subject and author index for Volume X will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows.

- 5701 HORMONE-ACTIVE TUMORS. (Ger.) Siegenthaler, W. (Bonn, West Germany), K. G. Zimmermann and G. Siegenthaler. *Langenbecks Arch Chir* 329:407-425, 1971.

Hormone-producing tumors can occur in endocrine and nonendocrine tissues. In endocrine organs, tumor-induced hormone production is characterized as *orthotopic* or *dystopic*, according to whether the tumor has invaded the endocrine structure of the gland itself or is found in hormone-active tissue dispersed from the parent organ. *Superimposed* hormone formation refers to increased release of glandotropic hormones due to tumor growth in the pituitary gland region. Ectopic hormone formation describes the secretion of hormones or substances with hormone-like effects by tumors in nonendocrine organs. The following tumor-induced hormones are discussed: antidiuretic, somatotrophic, thyroid stimulating, parathormone, calcitonin, aldosterone, renin, ACTH/cortisol, catecholamines, androgens, estrogens, choriogonadotropin, insulin, glucagon, gastrin, serotonin, and erythropoietin. Each hormone is classified according to tumor location, type of hormone formation, and clinical manifestation of tumor growth. The diagnosis and treatment of hormone-active tumors requires a knowledge of their activity in the system, particularly where surgical intervention is necessary. (84 references)

- 5702 EFFECT OF TROPICAL SUNLIGHT ON DEVELOPMENT OF RODENT AND SQUAMOUS CELL CARCINOMA. (E.) Belisario, J. C. (Sydney, Australia). *Int J Dermatol* 11(3):148-155, 1972.

The relationships between sunlight, skin pigment and skin cancer, especially basal cell (rodent) and squamous carcinoma are reviewed. The number of hours of sunlight exposure is a more important factor in skin carcinogenesis than the intensity of each exposure. Damage to collagen in the dermis by the UV component of sunlight causes degeneration which affects nutrition of the skin and plays an important part in skin carcinogenesis. Fair skins are more susceptible to sunlight UV damage than are darker skins. Accordingly, skin cancer incidence is high among fair-skinned residents of tropical latitudes (e.g., Australians), while it is low among tropical Negroes. Skin cancer is mostly an accompaniment of later life, and is more common in men than women (probably because men in general are more apt to work in sunlight-exposed circumstances than women). Factors which alter the amount of UV radiation reaching the earth, including altitude, ozone and cloud cover, affect skin cancer incidence. (49 references)

- 5703 THE CARCINOGENIC ACTION OF IONIZING RADIATIONS. (Rus.) Aleksandrov, S. N. (Cent. Res. Inst. Radiol., Moscow, USSR). *Vopr Onkol* 18(7):108-117, 1972.

Ionizing radiation has mutagenic and secondary proliferative effects. The mutagenic effect involves somatic cells undergoing radiation. The secondary proliferative effect involves the skin and endocrine

glands (such as thyroid and pituitary) with potential proliferative cells, but not organs or nervous system made up of ganglionic cells. The neoplasms developing due to irradiation depend on its dose. The optimal dose for carcinogenesis due to mutagenic and proliferative effects corresponds to 1700 r. From 7000-14,000 r, sterilization of cells occurs with suppression of carcinogenesis. Radiation-induced mutagenesis can itself cause neoplastic development, as in malignant changes of myeloid elements in myeloid leukemia. In many cases, radiation-induced blastomogenesis in tissues is conditioned by a combination of the mutagenic effect of radiation and unrelated effects, as in neoplasms of repeatedly resected irradiated liver. The carcinogenic effect of penetrating radiation is increased by various carcinogens such as urethane, carbon tetrachloride (which does not cause neoplasms by itself but causes neoplasms in combination with radiation), and dimethylbenzanthracene. The carcinogenic effect of ionizing radiation is due to activation of latent viruses, according to viral carcinogenesis theories. Radiation activation of viruses is not a necessary factor in the pathogenesis of neoplasms of radiation origin. (45 references)

- 5704 BILATERAL RETINOBLASTOMA: A DOMINANTLY INHERITED AFFECTION. (E.) Sorsby, A. (Royal Coll. Surgeons, London, England). *Brit Med J* 5813:580-583, 1972.

Data on the genetic transmission of bilateral retinoblastoma is briefly reviewed. In one study, eight of 14 children born to four mothers and three fathers with retinoblastoma had retinoblastoma; seven of these eight had bilateral retinoblastoma. In another study, 20 of 39 similar offspring were affected, 17 bilaterally. Bilateral retinoblastoma may be transmitted by individuals who are phenotypically normal. Individuals with retinoblastoma in one eye, who may pass as cases of sporadic unilateral retinoblastoma, may in fact have a suppressed bilateral condition. Five to ten percent of supposed unilateral retinoblastoma cases are actually cases of incompletely expressed bilateral condition. Bilateral retinoblastoma is a dominant disorder either in transmission or as a new mutation. (10 references)

- 5705 THE FINE STRUCTURAL CHANGES IN THE BASEMENT MEMBRANE AND TUMOR CELLS OF SQUAMOUS CELL CARCINOMA IN HUMAN SKIN. (E.) Moynahan, E. J. (Guy's Hosp. Med. Sch., London, England). *Ann Ital Derm Clin Sper* 25(2):199-203, 1971.

Microscopic examinations of the basement membrane in epidermal tumors are reviewed. The basement membrane separates epidermis from subjacent dermis. In UV-induced mouse squamous cell carcinoma, the basement membrane became thicker and patchy as malignancy progressed, and disappeared entirely with frank invasive malignancy. The basement membrane was found to remain intact in patients with

Bowen's disease and in mice with malignant and benign 7,12-dimethylbenz(a)anthracene-induced tumors. In senile keratosis lesions with associated squamous cell carcinoma, the basement membrane is disrupted at the dermo-epidermal junction. The membrane may also be disrupted at the dermo-epidermal junction in invasive lesions of the Borst-Jadassohn type. (11 references)

- 5706 PUBLIC HEALTH ASPECTS OF CANCER IN PET DOGS AND CATS. (E.) Dorn, C. R. (Dept. Community Hlth., U. Missouri, Columbia) and R. Schneider. *Am J Pub Health* 62(11):1460-1462, 1972.

Epidemiological evidence for horizontal transmission of leukemia from house pets to humans is briefly reviewed. All studies but one have shown no correlation between exposure to domestic animals (including dogs and cats) and leukemia incidence. An analysis of 300 families with a leukemia case and 831 randomly selected families were investigated showed an excessive leukemia risk for children exposed to sick or dead cats: 7.3% of children under 14 yr with leukemia had been exposed to sick or dead cats compared with 4.6% of control children. (18 references)

- 5707 CELL REPLACEMENT, AGEING, AND CANCER OF THE SKIN. (E.) Bullough, W. S. (Mitosis Res. Lab., U. London, England). *Ann Ital Derm Sper* 25(2):145-156, 1972.

The mechanisms which balance cell loss and cell production in skin tissues are discussed and applications to carcinogenesis are described. It has been shown that skin cells respond to trauma with increased mitosis, because of the loss of a mitotic inhibitor, epidermal chalone. Experiments with rabbit epidermal carcinomas, some of them highly anaplastic and malignant, and with rat granulocytic leukemias, indicated that tumor cells produced chalone. Because this chalone, which is probably a protein or glycoprotein, was quickly lost in the blood, the chalone content of tumor cells contained was less than 10% of normal. In addition, it was found that injecting chalone into tumor-bearing animals often caused temporary permanent tumor regression. (No references)

- 5708 VITAMIN B₁₂ AND THE TUMOR GROWTH PROCESS. (A LITERATURE REVIEW). (Rus.) Ostryanina, A. D. (Inst. Nutr., USSR Acad. Med. Sci., Moscow). *Vopr Pitan* (3):25-31, 1972.

Vitamin B₁₂ can affect division and growth of cells. Disturbances in vitamin B₁₂ exchange lead to disturbances in all cells of humans and animals. Vitamin B₁₂ is known to have a stimulating effect on cellular proliferation and DNA synthesis. Experimental data (with mice, hamsters, and guinea

pigs) show that vitamin B₁₂ accumulation in tissues promotes growth of tumors such as sarcomas. Consumption of vitamin B₁₂ by tumor cells is accompanied by decreased vitamin B₁₂ levels in the rest of the body, with resulting hypovitaminosis. Vitamin B₁₂ also activates tumors induced by various chemical carcinogens, such as dimethyl-aminoazobenzene, 2-acetylaminofluorene, dimethyl-benzanthracene, and methylcholanthrene. The effects of vitamin B₁₂ on the growth of neoplasms depend on the strain of the tumor, method of administration of vitamin B₁₂ to the body, and dosage. Large doses of vitamin B₁₂ seem to activate the growth of transplantable tumors in animals (rats), while small doses inhibit tumor growth. (71 references)

- 5709 PLEURAL MESOTHELIOMA AND ASBESTOSIS. (Fr.) Turiaf, J. (No affiliation). *El Torax* 20(1):117-124, 1972.

Pleural mesothelioma is an exceptional variety of malignant tumor of the pleura, diagnosed by its specific localization and histopathological findings of conjunctive epithelial proliferations. The connection between this tumor and asbestosis has been confirmed by many authors. If not the actual cause of mesothelioma, asbestos certainly favors its development. Other authors argue against the role of asbestos in this etiology, but it must be realized that in many cases the cancer does not develop until long after the subject has been exposed to asbestos (even after 40 yr). The cancer develops along the same lines as primary pleural tumors and can expand to the adjacent lung, the contralateral pleura, and to other areas nearby. Distant metastases are rare, since death intervenes between 6 and 18 months after the first appearance in the pleura. The histopathological picture is the same in mesotheliomas with or without asbestosis: cancer with a double epithelial and conjunctive potentiality; glandular and adenomatous aspects; angiod and fibrosarcomatous formations. In two observations of mesothelioma with asbestosis, pulmonary fibrosis was found only histologically and not through radiological evidence. There is no causal relationship between pulmonary fibrosis and mesothelioma. The mode of intervention of asbestos in carcinogenesis is not clear, but the presence of asbestos fibrils in the cytoplasm of mesothelial cells may have some etiological significance in this disease. (45 references)

- 5710 TUMOR-SPECIFIC ANTIGEN IN GI CANCER. (E.) Gold, P. (Dept. Med., McGill U., Montreal, Quebec, Canada). *Hosp Prac* 7(2):79-88, 1972.

The present state of knowledge of carcinoembryonic antigen (CEA) is reviewed. CEA, originally thought to be confined to tumors of the colon, has been found generalized to entodermally derived digestive system epithelium. It is a tumor-specific system-specific antigen, and is also found in fetuses of less than six months gestation. This may indicate that

appearance of CEA associated with tumors represents derepression of genetic information. Anti-CEA antibodies have been found in pregnant women, in patients with localized digestive system cancer, but in patients whose digestive system tumors metastasized out of their area of origin. CEA is water- and ammonium sulfate-soluble; it has a sedimentation coefficient of 7-8S; and its component carbohydrates include L-fucose, D-mannose, D-galactose, sialic acid and N-acetyl-D-glucosamine. (6 references)

11 AN IMMUNOSTIMULATION THEORY OF TUMOR DEVELOPMENT. (E.) Prehn, R. T. (Inst. Cancer Res., Philadelphia, Pa.) and M. A. Lappe. *Transplant Rev* 7:26-54, 1971.

Evidence suggesting that a low level of immune activity can stimulate rather than retard tumor growth is reviewed. The evidence is divided into three parts: (1) the role of the lymphoreticular system and immune reactivity in pregnancy; (2) lymphoid activity in relation to normal tissue development, regeneration, and grafting; and (3) evidence derived directly from oncogeny and tumor transplantation experiments. If, as a number of studies suggest, low levels of histo-incompatibility and immune reactivity facilitate fetal growth and survival, such conditions can reasonably be expected to facilitate tumor growth as well. Data on lymphoid and/or immune stimulation of normal tissues are in accord with an immunostimulation theory of tumor development. Direct support for the theory is provided by a 1964 study showing that allogeneic tumors grew better when exposed to weekly sensitized lymphocytes than when exposed to unsensitized lymphocytes. (160 references)

12 THE IMMUNOBIOLOGY OF HUMAN MALIGNANT DISEASE. (E.) Ritz, R. G. (Chicago Med Sch., Illinois). *Chicago Med Sch Quart* (1-4):40-44, 1972.

The current status of tumor immunology has its foundation in the vast amount of animal studies which have been conducted within the past 20 yr. From these studies and from numerous clinical observations, the concept of host-tumor interaction is evolved. Whereas antibody production is usually normal in cancer patients, their cell-mediated immunity seems to be impaired. The ability of cancer patients to manifest a delayed hypersensitivity response has been correlated with prognosis. Specific anti-tumor antibodies have been demonstrated in sera of patients with Burkitt lymphoma, malignant melanoma, and osteosarcoma. In addition, a specific tumor-associated antigen (carcinoembryonic antigen) is shown to be present in all human tumors derived from the endothelium of the gastrointestinal tract, and it was shown that all patients with localized cancers of this type produced antibodies against the antigen. Patients with metastatic gastrointestinal cancers lost their ability to

produce antibody. A similar fetal alpha globulin was detected in the blood of 70% of all patients tested who had primary hepatoma. Recent experiments have shown a common fetal antigen to be present in a wide variety of human neoplasms and in fetal tissues, but not in a large number of normal subjects. In some cases, however, the host response may be unable to eradicate the tumor cells since tumor antigen may be masked by antitumor antibody. The defective cell-mediated immunity seen in patients with advanced malignancies could be due either to a depletion of sensitized lymphocytes by the tumor mass or to production of a tumor- or host-directed substance which actually prevents the immune response. (26 references)

5713 ROLE OF HERPESVIRUSES IN MALIGNANT LYMPHOMA IN RABBITS. (E.) Hinze, H. C. (Dept. Med. Microbiol., U. Wisconsin, Madison) and P. J. Chipman. *Fed Proc* 31(6):1639-1642, 1972.

Herpesvirus sylvilagus, an indigenous virus of cottontail rabbits, produces a lymphoproliferative disease which varies in intensity from benign hyperplasia to apparent malignant lymphoma. Virus may be recovered from the cellular portion of the blood as well as from organs showing infiltration with immature, proliferating lymphoid cells. Fluorescent antibody staining, however, shows viral antigen only in a few small foci of cells scattered throughout the spleen and lymph nodes. The possibility is suggested that viral genome may persist in the abnormal lymphocytes without undergoing a complete cycle of virus replication. (11 references)

5714 ROLE OF HERPESVIRUS IN MAREK'S DISEASE, A MALIGNANT LYMPHOMA OF CHICKENS. (E.) Purchase, H. G. (Region Poultry Res. Lab., U.S. Dept. Agriculture, East Lansing, Michigan). *Fed Proc* 31(6):1634-1638, 1972.

Marek's disease was for years the most important cause of economic loss to the poultry industry. This highly infectious disease is characterized by lymphoid infiltration and uncontrolled proliferation in the nerves and visceral organs resulting in paralysis and tumor formation. It can be transmitted readily to genetically susceptible 1-day-old chickens with intact blood or tumor cells. A herpesvirus was isolated in cell culture and later was shown to be the cause of Marek's disease. The virus is highly cell-associated in the tissues and tumors of infected birds and in cell cultures. The feather follicle epithelium is the only location in the body where the virus becomes enveloped. From there it is shed into the environment accounting for the highly infectious nature of the disease. The virus is not transmitted congenitally. Some degree of control has been attained by breeding chickens for resistance to Marek's disease. Eradication of the disease has been possible on a limited scale by rearing chickens in isolation in houses supplied with biologically filtered air.

Several vaccines derived from Marek's disease virus or from a related virus of turkeys have been applied commercially with great success. This was the first neoplastic condition shown unequivocally to be caused by a herpesvirus and the first naturally occurring neoplasm for which a commercially applicable vaccine was developed. - 5715 POSSIBLE ROLE OF *HERPESVIRUS HOMINIS*, TYPE 2, IN HUMAN CERVICAL CANCER. (E.) Aurelian, L. (Johns Hopkins Sch. Med., Baltimore, Md.). *Fed Proc* 31(6):1651-1659, 1972.

Herpesvirus type 2 (HSV-2) has been associated with squamous cancer of the human cervix on the basis of sero-epidemiologic data. Similar studies designed to differentiate between three possible interpretations of this association are described. A herpesvirus, isolated from degenerated cervical tumor cells grown *in vitro* is identified as a type 2 on the basis of biologic and immunologic properties. Herpesvirus antigens and virus are not seen in duplicate cultures of viable cervical tumor cells. HSV-2 antigens are revealed by immunofluorescent techniques in exfoliated, but not in biopsied tumor cells from patients with the disease. The results are discussed in terms of the virus-host cells interaction; it appears that tumor cells harbor the viral genome in a repressed state. Exposure of the cells to high pH induces virus expression. (49 references)

- 5716 FETAL MOLECULAR FORMS OF ENZYMES IN HEPATOMA. (Fr.) Schapira, F. (Inst. Molec. Path., Paris, France) and A. Hatzfeld. *Biochimie* 54(5-6):695-700, 1972.

The fetal pattern of enzymes in certain cancerous tissues is reviewed. The resurgence in hepatoma of two aldolases of the fetal type was demonstrated by the determination of their relative activities with respect to fructose-1-phosphate (FIP) and to fructose-1,6-diphosphate (FDP). The ratio FDP/FIP is above 50 for aldolase A (muscle type), is equal to 1 for aldolase B (liver type) and is between 5 and 10 for type C (brain type). In fetal rat liver the ratio was about 6 on the 15th day of fetal life and decreased to less than 1.5 on the 21st day; in normal rat (or human) liver, this ratio was constant and very close to 1. In human fetal liver this ratio was about 2.0 between the 4th and 6th month and about 3.0 in the second month of gestation. The aldolase activity was moderately increased (1.2-3.0) in primary slow-growing hepatomas, but was extremely high in fast-growing hepatomas. Electrophoresis indicated that changes in the specificity of the aldolase in hepatomas were due to isozymes of muscle type aldolase in slow-growing and to isozymes of the brain type in fast-growing hepatomas. In the fetal liver, all three aldolases are present: aldolase B is hybridized with aldolase A and anodic isozymes are seen which resemble those of brain aldolase. In primary or transplanted slow-growing

hepatomas, the presence of aldolase A hybridized with aldolase B was confirmed, but no anodic isozymes were found. These were, however, clearly seen in fast-growing hepatomas and their migration was identical with those of brain aldolase isozymes. Immunological studies confirmed that slow-growing hepatomas contained a large quantity of aldolase A, whereas fast-growing hepatomas contained both muscle and brain types and very little hepatic aldolase B (less than 5%). It is suggested that in pathological conditions, particularly in carcinogenesis, the biosynthesis of the molecular enzymatic form is repressed, whereas the fetal form is not repressed. - 5717 CELLULAR DNA REPLICATION IN VIRAL INFECTION. (E.) Engsminger, W. D. (No affiliation) and I. Tamm. *Path Ann* 1:33-61, 1971.

The ability of different RNA- or DNA-containing viruses to inhibit cellular DNA replication is reviewed. Although appearing to multiply entirely in the cytoplasm, RNA viruses such as Newcastle disease virus (NDV), mengovirus, and reovirus profoundly affect cellular DNA replication. NDV and mengovirus infection also inhibit cellular RNA and protein synthesis, depression of cellular RNA synthesis by mengovirus occurring only after virus growth is complete. Results obtained with chemical inhibitors of protein synthesis strongly support the possibility that NDV and mengovirus inhibit cellular DNA synthesis secondary to inhibition of cellular protein synthesis. Inhibition of cellular DNA synthesis by reovirus is probably a direct effect of viral infection; it occurs in the absence of effects on cellular RNA or protein synthesis. It is unlikely that inhibition of cellular DNA synthesis by these viruses involves precursor depletion or interference with DNA polymerase and polynucleotide ligase. The inhibition probably results from a reduction in the number of active chromosomal sites of DNA replication in infected cells. Autoradiographic analysis of DNA replication in virus-infected cells showed that the length of the linearly arrayed segments of DNA synthesized in a 30-min period was equal to that in uninfected cells even when synthesis in infected cells was 70% inhibited. 62 LEUKEMIA EVOKED WITH 7,8,12-TRIMETHYLBENZ(A)-ANTHRACENE IN RAT. 1. CHANGES IN SPLEEN AND LYMPH. (E.) Bird, C. (Ben May Lab., U. Chicago, Ill.) and C. Huggins. *J Exp Med* 134(5):1285-1297, 1971.

Leukemia was evoked in a group of 12 male rats with four or five i.v. pulse-doses of 7,8,12-trimethylbenz(a)anthracene (7,8,12-TMBA), 30-35 mg/kg, at 10-day intervals beginning at age 28 days. The first evidence of leukemia was nodule formation in the spleen. Subsequently, the red pulp of the spleen was massively infiltrated with leukemic stem cells but malpighian corpuscles were not involved. The leukemic stem cells consisted of large mononuclear cells with vesicular nuclei, one or several prominent dark nucleoli, and variable amounts of basophilic cytoplasm; they were usually mixed with erythroblasts. Enzyme levels were determined in the spleens of 12 leukemic male rats age 82-145 days and ten untreated male controls of comparable age. In the spleens of the normal adult male rat, the activity of malate dehydrogenase (MDH) exceeded that of lactate dehydrogenase (LDH). In leukemic rats, LDH activity in the spleen was increased while MDH activity was reduced. Acid phosphatase activity in the spleen was significantly reduced in leukemia whereas alkaline phosphatase was increased. The initial effects of i.v. pulse doses of 7,8,12-TMBA, 30-35 mg/kg at 10-day intervals were followed in 36 male rats, eight of which were sacrificed three days after each pulse. The pulse doses markedly affected normal growth of spleen and thymus; however, only minimal changes occurred in the activity of critical enzymes measured after each dose of hydrocarbon.

763 MORPHOLOGY OF EXPERIMENTALLY INDUCED TUMORS OF THE SKIN IN THE RAT AND IN THE HAIRLESS MOUSE. (Ger.) Lau, M. (Path. Inst., U. Freiburg, West Germany), R. Rohrbach and C. Thomas. *Beitr Pathol* 146:33-54, 1972.

Diazo-acetic ester was used to induce skin tumors in rats (i.v.) and mice (i.p.) and these tumors were examined morphologically and compared with N-nitroso-compound induced tumors referred to in a previous experiment. The rats received weekly injections of 25 or 50 mg/kg diazo-acetic ester, in aqueous solution. The mice received semiweekly injections of 125 mg/kg of the carcinogen. Of 18 rats thus treated, 12 revealed tumors. The tumors were predominantly located in skin of the dorsal area and occasionally in the vicinity of the tail. They were epithelial tumors, squamous cell carcinomas and basal cell carcinomas. Among the premalignant changes, hyperplasias and papillomas of the epidermis, squamous epithelial cysts and sebaceous gland hyperplasias or adenomas were in the process of development. Of 40 mice, 12 died prematurely of pneumonia and the other 28 all developed skin tumors which were mainly papillomas and carcinomas, with one tumor resembling a basal cell carcinoma. The histological findings were about the same as those in the rat. These experimentally induced tumors are attributed to the absorptive action of

diazo-acetic ester, the tumors developing from epidermal cells or skin appendages. Exogenous carcinogens in the etiology of human tumors are discussed and the experimentally induced basal cell carcinoma is compared with the nodular ulcerative form of the human tumor.

5764 PROGRESSION IN MOUSE TUMORS INDUCED BY BP: CYTOGENETIC INVESTIGATIONS OF TUMORS, EXPERIMENTALLY INDUCED AND TRANSPLANTED METASTASES AND OF CELL LINES *IN VITRO*. (Ger.) Saul, G. (Inst. Cancer Res., German Acad. Sci., Berlin, East Germany) and R. Widmaier. *Arch Geschwulstforsch* 39(1):24-39, 1972.

Chromosome analyses were performed on monolayer cultures of six mouse primary tumors (PT) induced by s.c. injection of 1 mg benzo(a)pyrene, three primary metastases (PM) developing after i.v. injection of PT cells, and seven transplanted tumor metastases (TM). While *in vivo* tumor cell growth rate increased from PT to TM, *in vitro* growth rate decreased with tumor progression. Aneuploid and hyperdiploid cells were frequent in PTs. Hypotetraploid and tetraploid cells were also observed. The PT showed relatively few chromosome structural anomalies. All the PMs had cells with 80 or more chromosomes; two had many hyperdiploid cells; and two had many cells with altered chromosome structure. Transplanted metastases had mainly diploid, tetraploid, and cells with more than 100 chromosomes. Chromosomal anomalies included one PT with 17.5% cell breakage and frequent reunions; a PM with 25% breakage in chromosomes; a TM with frequent meta- and submetacentric chromosomes; and a TM with ring and allocyclic chromosomes. Tumor progression was by evolution with mutation and selection.

5765 INDUCTION OF HEART TUMORS IN RATS BY TREATMENT WITH METHYLNITROSOUREA. (Ger.) Schreiber, D. (Med. Acad. Erfurt, East Germany), H. Batka, R. Warzok and E. Quentin. *Zentralbl Allg Pathol* 115:31-39, 1972.

The induction of cardiac tumors by methylnitrosourea (MNU) in 72 out of 774 rats of both sexes and of two different strains, by various doses and two different routes of administration, is described. Group I consisted of Hauben rats administered 25 mg/kg MNU, four times weekly, i.v. (maximal dose 250 mg/kg) and developed 37 cardiac tumors within a mean latency period of 273 days. Group II received 20 mg/kg, four times weekly, i.p. (maximal dose 200 mg/kg) and developed 25 tumors within a mean latency period of 255 days. Group III received 10 mg/kg, biweekly, i.p. (maximal dose 180 mg/kg) and developed four tumors within a latency period of 211 days. The rats of groups II and III were also Hauben strain. Groups IV and V comprised Wistar rats who received 10 mg/kg MNU biweekly, i.v. and i.p., resp. (maximal dose 180 mg/kg) and developed four and two tumors, resp., the latency period being 284 and 290 days, resp., the incidence of tumor

formation was 10.5% in the Hauben rats and 4.1% in the Wistar rats; following i.v. injection of MNU, 8.1% of the animals developed cardiac tumors, while i.p. injections resulted in 11.6% tumor development. The effects of additional experimental conditions such as castration and testosterone administration were investigated in part of the population. In one group, whose ovaries had been extirpated prior to tumor induction, cardiac tumors were induced by MNU in 41% of the animals; other malignant tumors were also observed in combination with the cardiac tumors. The possibility of hormonal effects in the emergence of these tumors is discussed. The preferred location of the tumors was in the left ventricle. Morphologically, various developments from fibromas to spindle sarcomas and newly developed polymorph cell sarcomas were observed. A detailed study of the morphological picture may offer evidence of the origin of these tumors.

- 5766 ON A POSSIBLE BLASTOMOGENECITY OF DDT.
(*Rus.*) Shabad, L. M. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow), T. S. Kolesnichenko and T. V. Nikonova. *Vopr Pitan* 31(1):63-66, 1972.

The possible carcinogenic effect of DDT was studied in five consecutive generations of mice. Mice of line A received 10 mg/kg or 50 mg/kg of DDT daily from the age of 6-8 wk until the lactation period. Embryonal lungs were used for organ cultures 19-20 days from the beginning of pregnancy in each consecutive generation. A dose of 10 mg/kg DDT caused various changes in the organ cultures of all generations. Growth stimulation was seen in F₁, F₂, and F₃ generations. Diffuse and local hyperplasia of the epithelium increased with each generation: 8.9% in F₁, 16.4% in F₂, and 39.3% in F₃. The frequency of dystrophic changes in experimental cultures of F₁, F₂, and F₃ was lower than that in the control cultures, while it was higher in the experimental cultures of F₄ (30.1%) and F₅ (20.1%) than in the control cultures. Adenomatous changes were seen in the latter two generations. A 50 mg/kg dose of DDT had stronger transplacental effect. Hyperplastic changes were seen in 32.2% and adenomatous changes in 9.6% of F₁ cultures. Adenomas and other tumors were not observed in all organ cultures studied. It is concluded that the blastomogenic effect of DDT is weak.

- 5767 INDUCTION OF SMALL INTESTINAL CARCINOMAS IN RABBITS THROUGH METHYLNITROSOUREA.
(*Ger.*) Schreiber, D. (Med. Acad., Erfurt, East Germany), A. Lagerman and M. Geyer. *Zentralbl Allg Pathol* 115:40-47, 1972.

The induction of carcinomas of the small intestine in two groups of rabbits exposed to methylnitrosourea is reported. The sixty animals in Group I received 10 mg/kg methylnitrosourea i.v. at two wk intervals, while the 67 animals in Group II received 20 mg/kg of the carcinogen i.v. at four wk intervals. Tumor incidence was 25% in Group I and 68.7% in Group II. The first tumor appeared 194 days from the beginning

of the experiment. Most of the carcinomas (90%) appeared in multiple form. Metastases developed in the mesenteric lymph nodes, reticulum, peritoneum, and less often in the lungs and liver. Histologically, the picture was one of adenocarcinoma with prevalent scirrhous tumor formations. In their last weeks or months of life, the animals manifested loss of weight and diarrhea, ileus symptomatology or abdominal swelling with ascites. Species-dependent differences in the incidence and location of digestive tract tumors following methylnitrosourea administration are considered. In the rat, this carcinogen produces tumors in the forestomach, large intestine and only rarely in the small intestine.

- 5768 LUNG CANCER INCIDENCE AMONG CHLOROPRENE-HANDLING WORKERS. (*Rus.*) Khachatryan, E. A. (Fifth Clin. Hosp., USSR). *Vopr Onkol* 18(6):85-86, 1972.

A study of 2934 chloroprene-handling workers (working over 25 years) revealed 34 patients (1.24%) with lung cancer. The average age of these patients was 44.5 years and the average length of their service was 8.7 years. In the first control group of 4780 workers including chauffeurs, furniture makers, firemen, benzene storehouse workers, and house painters, there were 22 patients with lung cancer (0.46%). In the second group of 6045 workers including electricians, carpenters, electric welders, tinsmiths, and furnace workers, 11 had lung cancer (0.8%). There were only four patients with lung cancer (0.0064%) among 6220 office workers. Sixteen patients with lung cancer were found among the factory workers studied (number not given). Thus, the workers in contact with chloroprene showed a high incidence of lung cancer as compared with other occupational groups. Of the total 87 patients with lung cancer, 66 (75.8%) had chronic bronchitis, 3 (3.4%) tuberculosis, 1 (1.1%) bronchial asthma, and 4 (3.4%) pneumonia.

- 5769 THE ACTION OF PREGNANEDIOL AND ALLOPREGNANEDIOL ON THE CARCINOGENIC PROCESS IN PARADIMETHYLAMINOAZOBENZENE-TREATED MALE RAT LIVERS.
(*Fr.*) Lacassagne, A. (Fac. Med. Paris, France), M.-F. Jayle, L. Hurst and B. Desfosses. *C R Acad Sci [D] Paris* 274(1):141-143, 1972.

Two hypotheses concerning the mechanism of inhibition of p-dimethylaminoazobenzene (DAB)-induced rat liver canceration by progesterone and pregnenolone were tested. One theory attributed the inhibitory action of these steroids to the double bond at C-4 or C-5; the other attributed the effect to metabolites resulting from reduction of 21-desoxysteroids in the liver by 5- α -reductase, 5- β -reductase as well as by 3- and 20-hydroxy NAD-oxidoreductases, namely to pregnanediol and allopregnanediol. Male Wistar rats were fed a diet containing 600 mg/kg DAB plus 40 mg of 5 β -pregnanediol or 20 mg of 5 α -pregnane-3 β ,20 β -diol, 5 α -pregnane-3 β -ol-20-one or pregnenolone plus o,p'-DDD per kg of food. The two 5 α -steroids

had only a very weak or no effect on DAB-induced hepatocarcinogenesis, while 5 β -pregnanediol produced complete inhibition of hepatocarcinogenesis. Of the 13 rats fed the DAB- and pregnanediol-containing diet, none had precancerous lesions 452 days after the beginning of the experiment. Pregnenolone counteracted the degenerating effects of *o,p'*-DDD of the Leydig cells and prevented oncogenesis in 11 rats subjected to the combination treatment. Apparently, the double bond at C-4 or C-5 has no role in the inhibition of the DAB-induced carcinogenesis. The action of progesterone and pregnenolone, which are precursors of pregnanediol, seems to be mediated by this latter steroid. The configuration of the progesterone and pregnenolone metabolites appears to be decisive for their carcinogenesis inhibition effect: while the *trans*-configuration of the A and B rings of the 5 α -derivatives is inactive, the 5 β -pregnanediol with the A and B rings in a *cis*-configuration has a strong inhibitory effect on carcinogenesis.

5770 QUANTITATION OF CHEMICALLY INDUCED NEOPLASTIC TRANSFORMATION OF BALB/3T3 CLONED CELL LINES. (E.) DiPaolo, J. A. (Nat'l. Cancer Inst., Bethesda, Md.), K. Takano and N. C. Popescu. *Cancer Res* 32(12):2686-2695, 1972.

Cloned BALB/3T3 cell lines derived from a BALB/3T3 line are sensitive to the toxicity of known chemical carcinogens and undergo chemically induced transformation *in vitro*. A quantitative system of chemical transformation resulted in cell lines that caused fibrosarcomas when injected into mice (10^6 cells/mouse); no tumors developed from control lines (10^8). Transformation, indicated by criss-crossing of fibroblast-like cells not seen in controls, was scored in discrete colonies at 10 to 11 days or in foci after three weeks. Transformation was observed with carcinogenic polycyclic hydrocarbons, aflatoxin B₁, *N*-acetoxy-2-fluorenylacetyamide, and *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine but not with diethylnitrosamine or noncarcinogens. Transformation rate increased (based on transformed colonies/total colonies or original cell inoculum used), and cloning efficiency decreased as concentration of carcinogen was increased. The dose-response relationship was consistent with a one-hit phenomenon. The Poisson distribution of frequency of transformed colonies per dish indicates that transformation is due to induction. Transformed cell lines from carcinogen-transformed colonies or foci had decreased doubling time and increased saturation densities relative to control lines. Recloned, carcinogen-sensitive, BALB/3T3 cell lines present a reliable *in vitro* quantitative bioassay model for the study of chemical carcinogenesis.

5771 A DISTINCTION BETWEEN 3-METHYLCHOLANTHRENE AND ESTROGEN BINDING IN THE UTERUS. (E.) Toft, D. O. (Vanderbilt Med. Sch., Nashville, Tennessee) and T. C. Spelsberg. *Cancer Res* 32(12):2743-2746, 1972.

The binding of methylcholanthrene-³H to macromolecular components of the uterine cytosol fraction was analyzed and compared with the specific binding of estradiol to its receptor. Methylcholanthrene-³H binds to a component which sediments as a 5S complex on sucrose gradients and can be easily distinguished from the 8S estradiol-receptor complex. Unlabeled estradiol does not interfere with methylcholanthrene-³H binding, nor does unlabeled methylcholanthrene have any effect on the formation or sedimentation of the estradiol-³H-receptor complex. These results negate the possibility that the carcinogen acts in estrogenic target tissues by directly interfering with the normal interaction of estrogens with their receptor sites.

5772 THE CELLULAR ANALYSIS OF LIVER CARCINOGENESIS. VI. GROWTH AND ULTRASTRUCTURAL CHARACTERISTICS OF N-2-FLUORENYLACETAMIDE HYPERPLASTIC LIVER NODULE CELLS GROWN *IN VITRO*. (E.) Slifkin, M. (Allegheny Gen. Hosp., Pittsburgh, Pa.), L. P. Merkow, S. M. Epstein and M. Pardo. *Arch Path* 94(1):1-10, 1972.

Hyperplastic liver nodules (HLN) from male rats fed *N*-2-fluorenylacetyamide (*N*-2-FAA) for 15 wk were cultured *in vitro* and compared with malignant liver carcinoma tissue and normal liver tissue. HLN showed no evidence of malignancy. They were made up of uniform large cells which, in immunofluorescence, isotopic and ultrastructural studies, appeared to be hepatocytes. Growth dynamics of HLN distinguished them from liver carcinomas; HLN did not grow on glass surfaces, while carcinoma tissue did.

5773 REVERSIBILITY IN SKIN CARCINOGENESIS. (E.) Carter, R. L. (No affiliation), F. J. C. Roe and E. Hecker. *Ann Ital Derm Clin Sper* 25(2):222-226, 1971.

No tumors developed in female outbred Swiss mice given a single 100 μ g dose of 7,12-dimethylbenz(a)-anthracene (DMBA) on dorsal skin. When the single dose of DMBA was followed three wk later by a 15 wk course of twice weekly applications of Hecker Compound A₁ (HCA₁), a purified preparation of croton oil, 85% of treated mice developed one or more skin papillomas. In contrast, only 4% of mice developed papillomas when the interval between DMBA application and start of HCA₁ treatment was extended from three wk to one yr. Repeated applications of HCA₁ alone did not induce skin tumors. These results indicate that the tumor-initiating effect of 100 μ g DMBA is largely lost between 3-50 wk after its application to the skin.

5774 BINDING OF K-REGION EPOXIDES AND OTHER DERIVATIVES OF BENZ[a]ANTHRACENE AND DIBENZ[a,h]-ANTHRACENE TO DNA, RNA, AND PROTEINS OF TRANSFORMABLE CELLS. (E.) Kuroki, T. (Med. Sch., U. Wisconsin, Madison), T. E. Huberman, H. Marquardt, J. K. Selkirk, C. Heidelberger, P. L. Grover and P. Sims. *Chem-Biol*

Interact 4(6):389-397, 1972.

The binding of ^3H -labeled benz(a)anthracene (BA) and dibenz(a,h)anthracene (DBA) and their K-region epoxides, cis-dihydrodiols, and phenols to DNA, RNA and proteins of exponentially growing cells was studied. The epoxide of BA bound to all macromolecules purified from hamster embryo cells to a much greater extent (20 to 60 times) than the parent hydrocarbon or its other derivatives. The binding of the epoxide to DNA, RNA and protein reached a maximum after three hr, and thereafter gradually declined. The epoxide of DBA was highly bound to RNA and protein but not to DNA of the hamster embryo cells. The extent of binding of all compounds to DNA, RNA, and proteins of transformable mouse prostate cells was less than to hamster cells, and the binding to malignant mouse tumor cells was very much lower. From these and previously published results, it was concluded that, in at least some cases, the metabolism of hydrocarbons to epoxides is necessary for binding to macromolecules, for the production of mutations, and for malignant transformation.

- 5775 ORAL CONTRACEPTIVES AND CANCER. (E.)
Wendel, H. A. (U. Oregon Med. Sch.,
Portland). *Lancet* 2(7787):1139, 1972.

Animal toxicity data must be interpreted in terms of the therapeutic index derived from the ratio of the toxic to the therapeutic dose in the same species. The potential hazard of a drug to man cannot be estimated by expressing the toxic animal dose of the drug in multiples of its human therapeutic dose. Thus the wide safety margin for oral contraceptives indicated by tests in which mice and rats were given 50-400 times the human doses can only be regarded as spurious. Moreover, the period of exposure and the total amount of drug taken over time must be considered when evaluating the carcinogenic hazards. A woman on oral contraceptive medication takes in a yr two to three times more drug than the total amount tested in mice at the maximum (400 multiples) dose level.

- 5776 CHARGE TRANSFER IN THE MOLECULAR INTERACTION OF CARCINOGENIC 4-NITROQUINOLINE 1-OXIDES AND DNA, WITH SPECIAL REFERENCE TO ANALYSIS AT THE NUCLEOSIDE LEVEL. (E.) Okano, T. (Pharmaceut. Inst., Tohoku U., Sendai, Japan), A. Isebe and H. Matsumoto. *Gann* 63(4):427-436, 1972.

Calf thymus DNA or DNA nucleosides were mixed with 4,6-dinitroquinoline 1-oxide, 6-chloro-4-nitroquinoline 1-oxide, 4-nitroquinoline 1-oxide, 2-methyl-4-nitroquinoline 1-oxide, 4-nitroquinoline or quinoline 1-oxide. A recording spectrophotometer was used to measure visible difference spectra produced by quinoline interactions with DNA and deoxyribonucleosides. Difference spectra of DNA and each quinoline all showed a new absorption band in the visible region, as did spectra of

interaction systems containing quinolines and nucleosides. It was concluded that a π - π charge transfer between quinolines and the base moiety of the macromolecule played an important role in the DNA-quinoline interactions. Extent of charge transfer correlated with carcinogenicity for all quinolines except 4,6-dinitroquinoline 1-oxide, which showed a strong antitumor activity.

- 5777 CONTRIBUTION TO THE COCANCEROGENIC EFFECT OF CIGNOLIN IN ANIMALS. (Ger.) Langbein, W. (Radiol. Clin., Stralsund, East Germany). *Radiobiol Radiother (Berl)* 13(2):233-240, 1972.

Skin tests were conducted in male AB mice for the effects of a combination of tar and cignolin or a combination of 9,10-dimethyl-1,2-benzanthracene (DMBA) and cignolin. Ten groups of 20 animals each were tested: animals in first three groups received a single dose of 0.125 mg DMBA in 0.25 ml acetone (0.05%); animals in three other groups received five drop-treatments with 50% coal-tar solution in 0.25 ml acetone. Following an interval of one or two weeks, cignolin drops were applied in concentrations of 0.01, 0.03 or 0.05%. Three further groups were treated only with cignolin initially administered five times weekly, then three times and finally once weekly. The tenth group of mice served as the control. The application of cignolin to the skin of mice pretreated with DMBA or with tar promoted the formation of skin tumors in more than one-third of the animals. Following DMBA, the application of cignolin in increasing concentrations resulted in a tumor frequency of 62%. The first tumor appeared within 10 weeks, and in 20% of the animals of each experimental group, tumor formation occurred within about four months. With tar pretreatment, the tumor rate was only slightly dependent on cignolin concentration, with the highest tumor frequency (47%) after the 0.03% concentration. In tar-pretreated animals, the first tumor appeared two weeks following cignolin application; 20% of the animals exhibited tumors after five weeks. Cignolin application alone did not promote tumor development. Histologically, all the tumors were papillomas, some with numerous cell types and atypical nuclei, but without definite carcinomatous degeneration. Spontaneous regression of the tumors was observed in 21 out of 33 animals, even in some with multiple macroscopic tumors, after some weeks or months. The cocarcinogen effects of cignolin in animal experiments is discussed in connection with the use of cignolin in the treatment of psoriasis.

- 5778 SYNTHESIS OF HEPATOTOXIC AGENTS IN GERM-FREE AND CONVENTIONAL MICE WHICH HAD BEEN FED NaNO_2 AND DIMETHYLAMINE. (E.) Pollard, M. (Lobund Lab., U. Notre Dame, Ind.), N. Sharon and C. F. Chang. *Proc Soc Exp Biol Med* 140(3):1073-1076, 1972.

in vivo production of toxic agent(s) was demonstrated in conventional and germfree (GF) CFW and Swiss-Webster mice fed subtoxic doses of NaNO_2 and dimethylamine (DMA). Two responses were observed in the mice: acute death of some mice within 24 hr after simultaneous administration of the two drugs; and extensive necrosis in the livers of survivors. GF CFW mice tolerated 75 mg NaNO_2 , but this dose combined with 3500 mg DMA resulted in 100% mortality in 75 mice within 24 hr. Conventional CFW mice tolerated up to 150 NaNO_2 , while conventional and GF Swiss-Webster mice tolerated 100 mg NaNO_2 . However, these mice were toxic for many mice when administered with 100 or 3500 mg DMA. Microbial flora did not appear to be required for the *in vivo* synthesis of toxic agent(s) from NaNO_2 and DMA. The agent is assumed to be nitrosamine.

779 CYTOPHOTOMETRIC INVESTIGATIONS OF CELL NUCLEI FROM EXPERIMENTALLY INDUCED NEOPLASIA. (Ger.) Goerttler, K. (Inst. Exp. Path., U. Heidelberg, West Germany), D. Haag and C. Tasca. *Krebsforsch* 76(3):155-166, 1971.

The relationship between nuclear volume and nucleic acid content was studied as a measure of differentiation or initiation of neoplastic growth. For this purpose, hyperchromic tumors were induced in mouse skin with benzo(a)pyrene, and hypochromic tumors (hepatocellular adenoma) were induced in rats with diethylnitrosamine (DENA). Skin carcinomas and papillomas were produced in the subcutis of the NMRI mice by a single application of 0.1 ml of a 0.5% solution of benzo(a)pyrene in benzene, and hepatomas were produced in Sprague-Dawley rats by a daily dose of 3 mg/kg DENA in drinking water for a two-month period. A stochastic relationship was found (correlation coefficient of 0.85) between DNA content and nuclear volume in normal hepatocytes by means of cytophotometric determinations. After DENA administration, the cell nuclei in the still intact areas showed a much more marked eugenic reaction than nuclei in the epithelia of untreated animals, and tetraploid nuclei in the regenerating rat liver. The correlation between DNA content and nuclear volume in these cells was higher than in normal liver cells; this was due to the increased participation of cell nuclei with higher DNA content. This more marked correlation was expressed quantitatively in the higher slope of the regression line which reflects the relative acceleration in DNA synthesis following increased regeneration in the intact part of the liver. Increased aneuploidy was seen in advanced mouse skin carcinomas which was reflected in a rise in the regression lines with the concomitant increase of DNA values. The cytophotometric measurements of the DENA-induced hepatoma, however, showed increased nuclear volumes and a decrease in DNA content. The equation representing the correlation between DNA content and nuclear volume, $\text{DNA} = c \times \text{nuclear volume} + \text{constant}$ (where c is the degree of synchronization and the constant represents the degree of ploidy) may be applied in early detection of neoplastic processes.

5780 MUTAGENIC SELECTIVITY FOR THE RNA-FORMING GENES IN RELATION TO THE CARCINOGENICITY OF ALKYLATING AGENTS AND POLYCYCLIC AROMATICS. (E.) Fahmy, O. G. (Chester Beatty Res. Inst., London, England) and M. J. Fahmy. *Cancer Res* 32(3):550-557, 1972.

Drosophila melanogaster were exposed to a series of chemical carcinogens and the induction of mutant genes was observed. Marker genes observed for mutagenic activity of compounds included the RNA-forming loci *Minutes (M)*, an autosomal dominant, and *bobbed (bb)*, a sex-linked recessive. Nonspecific overall genetic damage, as indicated by X chromosome recessive lethals and visibles, was also observed. Test compounds included alkylating and nitroso compounds which react with cellular macromolecules, and nonreactive polycyclic hydrocarbons, aromatic amines, and azo dyes. Alkylating agents, represented by sulfur mustards (mustard gas and half-mustard gas) were mutagenically active on all investigated loci; nitroso compounds (including *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine and *N*-ethyl-*N'*-nitro-*N*-nitrosoguanidine) were also mutagenic on all loci investigated, though generally less so than sulfur mustards. General mutagenic activity on the X chromosome was invariably high with alkylating and nitroso compounds, but low or lacking with nonreactive compounds (including 3-methylcholanthrene, 7,12-dimethylbenz(a)-anthracene, acetylaminofluorene and diethylaminoazobenzene). Relative response to mutagens at the *bb* locus was measured as the ratio of the transmissible induced number of *bb* mutants to the corresponding X recessive lethals and visibles expected. Polycyclic aromatics gave ratios approaching unity while alkylating compounds gave ratios at least two orders of magnitude lower. Carcinogens among all chemical series were highly active on the *bb* loci.

5781 SHIFT OF TARGET ORGANS IN CYCASIN CARCINOGENESIS. (E.) Fukunishi, R. (Kagoshima U. Sch. Med., Japan), K. Watanabe, S. Terashi and K. Kawaji. *Gann* 62(5):353-358, 1971.

Rats were given cycasin orally in daily 4 mg/kg doses for life, in 50 mg/kg "pulse" doses weekly for 12 wk, or in a single 250 mg/kg dose. The small dose induced mammary adenocarcinomas in five of 29 Sprague-Dawley females and testicular tumors in six of 15 ACI mice. No mammary cancer was detected in ACI females and no testicular tumors in Sprague-Dawley males. The latent period of tumor induction was 349-595 days for mammary tumors and 704 days for testicular tumors. Multiple pulse doses of cycasin and a single large dose caused intestinal tumors in tested Sprague-Dawley rats, but the incidence was higher (81.3%) in the 16 males of each group. The latent period was 323.3 days \pm 31.4 days in the pulse-dose group and 414.4 days \pm 94.6 days in the large-dose group. Kidney tumors, including ten nephroblastomas and six adenocarcinomas, were induced in 11 of 15 females in the large-dose group. The latent

period was 349.9 days \pm 83.2 days. Cirrhosis of the liver (three cases) and hepatomas (five cases) were found only in the pulse-dose group.

5782 PATHOLOGY OF CARCINOMA OF THE LUNG ASSOCIATED WITH ASBESTOS EXPOSURE. (E.)

Kannerstein, M. (Barnert Mem. Hosp. Ctr., Paterson, N.J.) and J. Churg. *Cancer* 30(1):14-21, 1972.

A retrospective study was conducted on the morphologic, anatomic and histologic characteristics of carcinoma of the lung in 50 males with a history of asbestos exposure. The data were compared with similar data obtained from the records of 50 randomly chosen males who had lung carcinoma without a history of asbestos exposure. Although no difference between the two groups was found in the histologic cell types, the position of tumors within a lobe, or the incidence of metastases, the two series differed significantly in the distribution of tumors in relation to upper and lower lobes. Lower lobe tumors predominated in the asbestos-associated cases (19 lower lobe vs 13 upper lobe tumors), while upper lobe tumors predominated in the controls (29 upper lobe vs 12 lower lobe tumors). The asbestos-exposed group also showed a somewhat higher frequency of severe pleural involvement although its significance was questionable. The similarities between the lung tumors found in the control and in the asbestos-exposed groups were consistent with previously published epidemiologic and experimental studies indicating that asbestos functions as a cocarcinogen rather than as a carcinogen.

5783 HIGH YIELD OF HEPATIC TUMORS IN RATS BY CYCASIN. (E.) Fukunishi, R. (Kagoshima U. Sch. Med., Japan), S.-I. Terashi, K. Watanabe and K. Kawaji. *Gann* 63(5):575-578, 1972.

Hepatic tumors were induced in male and female Sprague-Dawley rats by continuous administration of 10 mg/kg/day of cycasin (a component of the seeds of cycads) in drinking water beginning at age 21 or 50 days. Liver tumor incidence was 80-90% in all groups. The latent period of tumor induction was 167-480 days in the 21-day-old groups and 251-556 in the 50-day-old groups. Autopsy and histologic examination of all tumor-bearing rats revealed both hepatomas and hepatic sarcomas. Hepatomas, whose incidence was slightly higher than that of hepatic sarcomas in all but the 50-day-old male group, were often disseminated into the peritoneal cavity. Lung metastases were observed in nine of 35 cases. The sarcomas, which were predominantly fibrosarcomas, showed moderately atypical spindle-shaped cells. Mitotic figures were abundant. In addition to the liver tumors, a small number of tumors of other sites was seen (kidney, intestine, thymus and ear duct). There were no apparent age or sex differences in the incidence of the hepatic tumors other than the higher incidence of hepatic sarcomas in older males.

5784 THE TRANSPLACENTAL EFFECT OF DIMETHYLBENZANTHRACENE (DMBA) AND ITS NONCANCEROGENIC ANALOGUE-ANTHRACENE--IN ORGANIC CULTURES OF MOUSE EMBRYONAL KIDNEYS. (Rus.) Sorokina, Yu. D. (Inst. Exp. Clin. Oncol., Acad. Med. Sci. USSR, Moscow). *Biull Eksp Biol Med* 72(9):86-89, 1971.

The organ cultures of 19-21 day embryonal kidneys from mice (C57BL x CBA) which had received 7,12-dimethylbenzanthracene (2 mg x 4) and anthracene (2 mg x 4) in the last week of their pregnancy were incubated and studied electron-microscopically. The viability of cultures grown for 26 and 30 days was greater in both experimental groups (8/36 in the anthracene group and 21/49 in the 7,12-dimethylbenzanthracene group) than in the control group (0/27). Hyperplastic changes of the epithelium after introduction of anthracene and 7,12-dimethylbenzanthracene were similar, but their intensity and frequency were higher in the 7,12-dimethylbenzanthracene group (30.9%, 42/179) than in the anthracene group (15.6%, 24/205).

5785 REGIONAL AND PERIPHERAL LYMPH NODE LYMPHOCYTIC NUCLEI DNA CONTENT UNDER METHYLCHOLANTHRENE-INDUCED CARCINOGENESIS CONDITIONS. (Rus.)

Gudim-Levkovich, K. A. (Inst. Exp. Clin. Oncol., Ukrainian SSR Acad. Sci., Kiev, USSR), L. P. Lysyuk, and Yu. A. Umanskiy. *Vopr Onkol* 18(2):60-64, 1972.

The DNA content of the nuclei of regional and peripheral lymph node lymphocytes was studied after tumor induction by methylcholanthrene. Methylcholanthrene (1 mg/0.1 ml peach oil) was injected into the right hind paw of BALB/c mice. The mice were decapitated one to four months after the carcinogen introduction. The DNA levels of the nuclei of regional (right inguinal) and peripheral (left axillary) lymph node lymphocytes were determined by their optic density. Before methylcholanthrene administration the DNA content of the lymphocytic nuclei of the peripheral lymph nodes was essentially the same as that of the regional lymph nodes. In the process of tumor development (one to two months after the carcinogen introduction) in the mice, there was an increase in the DNA content of the lymphocytic nuclei of both regional and peripheral lymph nodes. This was due to an increase in the number of the nuclei whose DNA content was increased with respect to the diploid set of chromosomes. In the pretumor period, i.e., three months from the carcinogen introduction, the DNA content in the nuclei of the small lymphocytes of the regional lymph nodes was higher than that of the peripheral lymph nodes. After four months, when the tumors had actually developed, the DNA content in the lymphocyte nuclei of the regional lymph nodes was lower than that of the peripheral lymph nodes.

5786 ATYPICAL LYMPHOPROLIFERATIVE AND EPITHELIAL LESIONS OF THE HAMSTER

CHEEK POUCH INDUCED BY TOPICAL EXCESS OF VITAMIN A. (E.) Polliack, A. (Hadassah U. Hosp. Med. Sch., Jerusalem, Israel) and I. S. Levij. *Ann Ital Derm Clin Sper* 25(2):184-191, 1971.

The right cheek pouches of 48 Syrian hamsters were painted with vitamin A palmitate three times/wk for 2-12 wk. The animals were sacrificed after treatment and both cheek pouches were examined histologically. No changes in treated cheek pouches were noted after two wk. After four wk, there was a diffuse, subacute inflammatory infiltrate in the lamina propria. Focal acanthosis with formation of rete pegs was observed. Focal epithelial hyperplasia progressed with continued treatment and eventually led to the development of foci of marked epithelial atypia. In the latter stages, there were dense mononuclear cell infiltrates in the lamina propria and muscular wall. The infiltrates consisted mainly of lymphocytes and resembled the lymphoreticular hyperplasia seen in malignant lymphomas.

5787 CARCINOGENS AS FRAMESHIFT MUTAGENS: METABOLITES AND DERIVATIVES OF 2-ACETYL-AMINOFLUORENE AND OTHER AROMATIC AMINE CARCINOGENS. (E.) Ames, B. N. (Biochem. Dept., U. California, Berkeley), E. G. Gurney, J. A. Miller and H. Bartsch. *Proc Nat Acad Sci USA* 69(11):3128-3132, 1972.

The potency as frameshift mutagens of several metabolites of carcinogenic chemicals was studied by adding metabolites in crystalline form to cultures of *Salmonella typhimurium*. The mutagenicity tests used four *Salmonella* strains which require histidine. The test measured the effect of putative mutagens on the reversion to growth of the strains in histidine-free media. The potency of fluorene derivatives as frameshift mutagens was in the order: 2-nitroso > N-hydroxy-2-amino >> N-hydroxy-2-acetyl-amino > 2-amino. 4-Nitrosobiphenyl, 4-nitroso-trans-stilbene, 2-nitrosonaphthalene and 2-nitrosophenanthrene were also potent frameshift mutagens. The compounds may be mutagens of the type that intercalate into DNA and react covalently with it.

5788 SERUM ALPHA-FETOPROTEIN. VIII. SERUM LEVELS DURING DIETHYLNITROSAMINE POISONING OF BABOONS. (E.) Purves, L. R. (Div. Life Sci., Atomic Energy Board, Pretoria, South Africa). *Int J Cancer* 10(3):552-556, 1972.

Serum alpha-fetoprotein (AFP) levels during various stages of poisoning of baboons with diethylnitrosamine (DENA) were determined by a radioimmunoassay method. A group of three young baboons given five i.p. injections of 20 mg/kg DENA showed a dramatic increase in AFP. This effect was repeated during subsequent treatment with 5 mg/kg DENA administered orally three times a wk, and the AFP peaks were paralleled by rises in serum alkaline

phosphatase. Weight gain was affected and treatment was stopped on days 64, 135, and 256. After a 150-day lag, there was a sudden spurt of growth, alkaline phosphatase reached a peak and a transient increase in AFP occurred. The response to more DENA after day 560 was a rise in AFP unaccompanied by a rise in alkaline phosphatase. With continued DENA treatment, serum AFP rose or fell in individual animals. No animal has yet manifested clinical signs of a liver tumor. Three possible mechanisms of AFP synthesis in human disease are discussed.

5789 QUANTITATIVE ASPECTS OF TRANSPLACENTAL TUMOR INDUCTION WITH ETHYLNITROSOUREA IN RATS. (E.) Swenberg, J. A. (Dept. Vet. Pathobiol., Ohio State U., Columbus), A. Koestner, W. Wechsler and R. H. Denlinger. *Cancer Res* 32(12):2656-2660, 1972.

Dose-response relationships of transplacental tumor induction with the resorptive carcinogen, ethylnitrosourea, were investigated in Sprague-Dawley and Fischer rats. Neuroectodermal tumors were produced in offspring of all rats exposed to a single dose of ethylnitrosourea, 1, 5, 20, or 50-mg/kg, near the end of gestation. The incidence of experimentally induced neoplasms was directly proportional to the dose of carcinogen, while mean survival time was inversely related to exposure. The incidence of tumors varied with the dose of carcinogen and strain of rat. Brain tumors were the cause of death for 69% of the Fischer rats exposed to ethylnitrosourea, 50 mg/kg, whereas only 27% of similarly exposed Sprague-Dawley rats died of brain tumors. A significantly longer survival time was demonstrated for rats that died of gliomas compared with those that died of neurinomas or ependymomas. The investigation demonstrates that the age at which an animal develops neoplasia following transplacental exposure to a carcinogen depends on the level of exposure and the tumor type. It is suggested that tumors of adults, as well as of children, may be due to transplacental exposure to carcinogenic agents.

5790 CHEMILUMINESCENCE COUPLED WITH THE FORMATION OF LIPID PEROXIDES IN BIOLOGICAL MEMBRANES. VI. EFFECT OF CARCINOGENIC HYDROCARBONS ON THE LUMINESCENCE AND ACCUMULATION OF PEROXIDES IN THE MITOCHONDRIA. (E.) Tafel'shtein, E. Ye. (Second Moscow State Med. Inst., USSR), O. E. Utkin and V. A. Vladimirov. *Soyuzdiz* 16(5):949-951, 1971.

Mitochondria were treated, in the presence of the ions of bivalent iron, with 7,12-dimethylbenz(a)-anthracene, 3-methylcholanthrene, benzo(a)pyrene, or anthracene. The intensity of chemiluminescence was increased two- or three-fold by treatment with the carcinogens. However, the agents did not affect the accumulation of lipid peroxides (malonic dialdehyde) in mitochondria. The intensification of chemiluminescence was apparently the result of energy migration to the hydrocarbons.

- 5791 THE EFFECT OF LONG-TERM EXPOSURE TO DDT ON CF-1 MICE. (E.) Tomatis, L. (Int. Agency Res. Cancer, Lyons, France), V. Turusov, N. Day and R. T. Charles. *Int J Cancer* 10(3):489-506, 1972.

CF-1 minimal inbred mice were given technical DDT mixed into the diet at the dose levels of 2, 10, 50 and 250 parts per million (ppm) for the entire life span for two consecutive generations. Exposure to all four levels of DDT resulted in a significant increase of liver tumors in males, this being most evident at the highest level used. In females, the incidence of liver tumors was slightly increased following the exposure to 10 and 50 ppm, while a marked increase was observed following exposure to 250 ppm. In DDT-treated animals the liver tumors were observed at an earlier age than in untreated controls. The age at death with liver tumors and the incidence of liver tumors appeared to be directly related to the dose of DDT to which the mice were exposed. Four liver tumors all occurring in DDT-treated mice, gave metastases. Histologically, liver tumors were either well-differentiated nodular growths, pressing but not infiltrating the surrounding parenchyma, or nodular growths in which the architecture of the liver was obliterated showing glandular or trabecular patterns.

- 5792 URETHAN AND X-RAY EFFECTS ON MICE OF A TUMOR-RESISTANT STRAIN, X/Gf. (E.) Goldfeder, A. (Dept. Hlth. Hosp., New York U., New York). *Cancer Res* 32(12):2771-2777, 1972.

Inbred X/Gf mice with an extremely low incidence of spontaneous neoplasms were tested for their response to urethan and X-irradiation. Newborn, infant, and adult mice of both sexes were treated weekly with various doses of urethan [0.5 mg/g body weight (7 times) for newborn mice; 1.0 mg/g body weight (12 times) for infant and adult mice applied i.p., and 24 mg/mouse/week applied cutaneously]; with X-irradiation ranging from 300 rads (1 time) to 80 rads (10 times) and with combined treatments [urethan, 1.0 mg/g body weight (4 to 12 times) and X-irradiation, 75 to 150 rads (4 times)]. The incidence of neoplasms was very low in all age groups regardless of the mode of treatment, and it reached 3.4% for the total of 1023 mice. The only statistically significant difference was noticed between the group subjected to combined treatments and pooled data on all experimental groups ($p < 0.05$ for the "both-tail" test). Differences between other modes of treatment and between pooled data for both sexes were not statistically significant. Among 38 recorded neoplasms, 18 were thymomas of the lymphoblastic type, 13 were thymomas of the lymphocytic type, three were reticulum cell sarcomas, and four were mammary tumors. The very low incidence of neoplasms induced by urethan and X-irradiation in X/Gf mice is explained on the basis of (a) their high endogenous immune competence, (b) the absence of leukemia viruses, and (c) the very low incidence of mammary tumor virus.

- 5793 AGGREGATE-FORMING ABILITY OF LIVER CELL LINES DERIVED FROM DAB-FED RATS IN ROTATION CULTURE. (E.) Chikata, E. (Okayama U. Med. Sch., Japan). *Acta Med Okayama* 25(1):57-64, 1971.

Five liver cell lines from rats fed diethylaminoazobenzene (DAB) for different lengths of time were grown in rotation cultures for 3 to 8 days. The size of aggregates formed by cells from DAB-fed rats was observed. It was found that cell lines from rats fed DAB for longer periods in general produced larger aggregates. Differences in aggregate formation between cell lines were apparent after 24 hr in rotation cultures, but became more pronounced after three days of culture. Histologically, aggregates from cell lines cultured for three days consisted of cuboidal epithelial cells.

- 5794 A CASE CONTROL STUDY INTO THE POSSIBLE EFFECTS OF BIRTH CONTROL PILLS ON PRECLINICAL CARCINOMA OF THE CERVIX. (E.) Worth, A. J. (Brit. Columbia Cancer Inst. Vancouver, Canada) and D. A. Boyes. *J Obstet Gynaecol Br Commonw* 79(8):673-679, 1972.

A study was conducted to determine the possible effects of birth control pills and socio-economic factors on the development of preclinical squamous cell carcinoma of the cervix in 310 women between the ages of 20 and 30 in the Province of British Columbia, Canada. The data were collected by questionnaires during 1969 and 1970 and were tabulated by the Division of Vital Statistics, British Columbia. No difference was noted between the positive cases and 682 matched controls in the mean interval between first use of oral contraceptives and entry into the study. There were also no difference in the overall usage of contraceptives, the type of hormonal contraception used, the household income, or religion. The use of the different contraceptive methods in the screened population of the entire province of British Columbia was similar to that of the selected case control study group, except for a slightly lower incidence of usage of sequential preparations in the overall population. The positive case group did have a higher incidence of separations, divorces, abnormal marital situations, and marital and extramarital pregnancies than did the control group. This suggested that the pattern of social behavior, rather than the use of oral contraceptives, was a more likely cause of the increased incidence of preclinical cervical carcinoma in the positive group.

- 5795 COFFEE AND BLADDER CANCER. (E.) Zeitlin, B. R. (General Foods Corp., Technical Ctr., White Plains, N.Y.). *Lancet* (7759):1066, 1972.

Instant-coffee solids were administered for two years to male and female Sprague-Dawley rats, starting at age 21 days. The 144 males and 144 females consumed the equivalent of 85 cups of strong coffee

ly (6.7 g caffeine/cup). Histopathological examination of the urinary bladders of 94 males and females showed no abnormalities related to the free diet. No tumors were found and hyperplasia of the bladder epithelium was not observed. Only one rat, a control, had bladder stones. These results do not support an epidemiological study suggesting an association between coffee drinking and bladder-cancer risk.

6 CARCINOGENESIS IN TISSUE CULTURE. 19: PHOTODYNAMIC ACTION OF 4-NITROQUINOLINE OXIDE (4NQO) ON MAMMALIAN CELLS IN CULTURE. (E.) Tsutsu, H. (Inst. Med. Sci., U. Tokyo, Japan) and T. Takaoka. *Jap J Exp Med* 42(4):341-354, 1972.

Photodynamic action of 4NQO on the following six cell strains was exhibited in culture; 1 strain derived from normal rat liver cells, 2 from rat liver cells transformed, 1 from rat ascites hepatoma L-929 and its substrain. Cells were treated after two weeks of culture with $3.3 \times 10^{-6}M$ 4NQO only once for 10 min in the dark and subsequently by irradiation with 365 nm light for 120 min. The cultivation was carried out at 37°C in the dark. Most of the strains showed severe cell degeneration and destruction by 4NQO-treatment alone depending upon 4NQO concentration, but the cytotoxic effect was markedly enhanced by additional irradiation. This enhancing effect of irradiation was gradually reduced with time after 4NQO-treatment, e.g., when irradiated four days after 4NQO-treatment, cells were able to maintain their growth. Irradiated 4NQO was remarkably low in its cytotoxic effect. Irradiated medium showed low toxicity to cells. A substrain of L which had been serially grown in a protein- and lipid-free synthetic medium showed a response quite different from that of the others including its parent L-929 which was resistant to irradiation; the substrain was highly resistant to 4NQO but extremely sensitive to irradiation.

7 CELL DIVISION IN NORMAL AND NEOPLASTIC MAMMARY GLAND TISSUE IN THE RAT. (E.) Hamme, R. E. (Fac. Med. Dent., U. Manitoba, Winnipeg, Canada) and F. D. Bertalanffy. *Anat Rec* (1):1-7, 1972.

Mitotic rates of epithelial cells in female Sprague-Dawley rat mammary glands were determined in virgin rats, and during pregnancy, lactation and involution. Mitotic rates were determined for mammary tumors induced by a single administration of 7,12-dimethylbenz(a)anthracene (DMBA) via gastric intubation. Mitotic rates were determined from sectioned tissues taken from rats 6 hr after colchicine injection. The mitotic rate of virgin mammary epithelium was 1.69% and showed no apparent diurnal variation. On the 12th day of pregnancy, the mitotic rate increased to 13.2% and it showed a statistically significant diurnal fluctuation. On the second day after parturition, the mitotic rate again returned to very low levels (0.51%) and remained low (0.73%) throughout the period of lactation. The mitotic

rates of 19 DMBA-induced mammary tumors, which varied from 0.39% to 8.43%, showed a definite correlation with the histologic grade of the tumor, with the anaplastic tumors having the highest mitotic rates.

5798 THE RELEVANCE OF CHEMICO-BIOLOGICAL INTERACTIONS FOR THE TOXIC AND CARCINOGENIC EFFECTS OF AROMATIC AMINES: V. THE PHARMACOKINETICS OF RELATED AROMATIC AMINES IN BLOOD. (E.) Groth, U. (Max Planck Inst. Biochem., Munich, Germany) and H.-G. Neumann. *Chem-Biol Interact* 4(6):409-419, 1971/72.

Young adult Wistar rats were given 1.2 mg of tritium-labeled carcinogenic (*trans*-4-dimethylaminostilbene (*trans*-DAS), noncarcinogenic *cis*-4-dimethylaminostilbene (*cis*-DAS), or 4-dimethylaminobiphenyl (DABB) by stomach tube. Blood was removed, and plasma and erythrocytes were isolated and analyzed for radioactivity. Blood levels of tightly bound radioactivity were higher in rats given *trans*-DAS than in rats given *cis*-DAS or DABB. This difference may have been due to differential binding of radioactivity to plasma proteins and red cell constituents; most radioactivity was carried by hemoglobin. When blood from treated rats was subjected to gel filtration on Sephadex G-200, total radioactivity in blood was again two or three times higher in rats given *trans*-DAS. However, radioactivity was associated with plasma proteins to a comparable extent for all three substances. Most *cis*-stilbene and biphenyl activity in plasma proteins was only loosely bound and could be extracted with organic solvents. Only part of the *trans*-stilbene activity was extractable in this way. Erythrocytes contained considerable more radioactivity after administration of *trans*-DAS than after the other two agents. On gel filtration, most radioactivity migrated with hemoglobin and was only partly extractable with organic solvents. When rats were given unlabeled *trans*-DAS and DABB, the pattern of unbound metabolites in plasma analyzed by radio gas chromatography was very similar to that in liver and kidney. In rats given labeled and unlabeled compounds, more than 90% of *trans*-aminostilbene and 55% of *trans*-acetylaminostilbene in blood were bound to hemoglobin in an extractable form.

5799 LEUKAEMIA EVOKED WITH 7,8,12-TRIMETHYLBENZ(A)ANTHRACENE IN RAT III. CHANGES IN LYMPHOID TISSUES. (E.) Bird, C. C. (Ben May Lab. Cancer Res., U. Chicago, Illinois) and K. Mainzer. *Br J Cancer* 26(5):373-379, 1972.

Profound changes in the level of certain dehydrogenase enzymes were observed in lymphoid tissues of rats involved by erythroblastic stem cell leukemia. In lymphoid tissues free of leukemic involvement, activity of malate dehydrogenase (MDH) always exceeded that of lactate dehydrogenase (LDH). In those which contained substantial infiltrates of

leukemic cells, activity of LDH was increased while MDH activity was reduced. In leukemic spleen significant changes were observed in the molecular forms of LDH; the proportion of LDH-5 (muscle-type LDH) was greatly increased while the other molecular forms were reduced. The spleen of rats with leukemia exhibited a marked increase in the normal level of aerobic and anerobic glycolysis but the rate of respiration was unchanged. The terminal stages of stem cell leukemia in the rat are characterized by wide-spread leukemic infiltration of liver and other tissues. Lymph node involvement, however, was found to be selective. Coeliac lymph nodes greatly exceeded other lymph node groups in their incidence of leukemic involvement. It is considered that the selective nature of lymph node involvement in stem cell leukemia derives from topographical considerations.

5800 CHANGES IN THE COMPOSITION OF RAT LIVER CHROMATIN FRACTIONS DURING DIETHYLNITROSAMINE CARCINOGENESIS. (E.) Gronow, M. (Dept. Exp. Path. Cancer Res., U. Leeds, England). *Biochem J* 130(1):11, 1972.

Attempts were made to prepare and characterize chromatin fractions from liver nuclei of rats which had received the carcinogen, diethylnitrosamine, in their drinking water for 70 days. Centrifugation of nuclear sonicates resulted in three chromatin fractions (I, II and III) which contained 12, 64 and 24%, resp., of the total cellular DNA. The specific activities of fractions I and II prepared from animals which had been given ^3H -orotate were the same, whereas that of fraction III was three to four times greater. Preliminary results indicated that there was no difference in specific activity between the three chromatin fractions prepared from normal livers of control rats. Polyacrylamide gel electrophoresis of non-histone proteins from the three chromatin fractions showed that, except for the loss of one polypeptide ($M_w=15,500$) from fraction III of carcinogen-treated rat livers, there was no difference.

5801 RAPID INDUCTION OF SARCOMAS IN RATS BY COMBINATION OF NICKEL SULFIDE AND 3,4-BENZPYRENE. (E.) Maenza, R. M. (U. Connecticut Hlth. Ctr., Farmington), A. M. Pradhan and F. W. Sunderman, Jr. *Cancer Res* 31:2067-2071, 1971.

Male Fischer strain rats were injected bilaterally in the thigh muscles with a suspension containing 10 mg nickel sulfide powder and 5 mg 3,4-benzpyrene powder. Both the mean latent period for tumor development and the mean survival time of rats which received the nickel-benzpyrene injections were significantly shorter than those of animals which received only nickel or only benzpyrene. No tumors developed in control rats which received only injection vehicle. The proportion of sarcomas which developed at the site of injection and which were classified histologically as rhabdomyo-

sarcoma was 91% in the group injected with nickel-benzpyrene compared with 81% in the group injected with nickel and 13% in the group receiving benzpyrene only. The incidence of metastases to lungs and regional lymph nodes was equally higher in the nickel-benzpyrene (53%) and nickel-treated (57%) groups than in the benzpyrene-treated group (20%). These results provide additional support for a possible carcinogenic interaction between nickel compounds and polycyclic hydrocarbons.

5802 A REINVESTIGATION OF EPIDERMAL TRANSPLANTATION DURING CHEMICAL CARCINOGENESIS. (E.) Steinmuller, D. (U. Utah Med. Ctr., Salt Lake City). *Cancer Res* 31:2080-2084, 1971.

A study was undertaken to determine whether carcinomas produced by topical application of a carcinogen are due to direct carcinogenic action on the epidermis or to indirect effects on the dermis ("stromal permutation hypothesis.") (C57BL/6xBALB/c) F_1 hybrid mice received topical applications of 0.3% methylcholanthrene (MCA) once a wk for 12 wk. Two wk after the final MCA treatment, the epidermis at the site of application was removed and all treated mice received a transplant of epidermis from one of the untreated inbred parental strains. This technique thus provided a strong (H-2) histocompatibility marker for determining the origin of the tumors which subsequently developed. Of the 14 carcinomas which arose at the graft sites in the F_1 primary hosts, none grew progressively in the parental strains; however, all grew in the F_1 host cells. In previously reported tests of the stromal permutation hypothesis, the bases of hair follicles had been left intact in the preparation of the graft beds in the MCA-treated hosts. In addition, histocompatibility markers had not been employed. Therefore, the possibility had existed that the tumors which arose in the grafts actually arose from the residual epithelial tissue and not from untreated epidermal grafts. The results from the current study indicate that this latter possibility was indeed true and that the original interpretation in favor of stromal permutation was incorrect.

5803 INFLUENCE OF POLLUTANT GASES ON BENZPYRENE HYDROXYLASE ACTIVITY. (E.) Palmer, M. S. (Environmental Protection Agency, Research Triangle Park, N.C.), R. W. Exley and D. L. Coffin. *Arch Environ Hlth* 25(6):439-442, 1972.

Rabbits were exposed for three hr to ozone (O_3) or nitrogen dioxide (NO_2); immediately after exposure, or one, three or seven days after exposure, rabbits were killed and tracheobronchial mucosa was assayed for benzo(a)pyrene hydroxylase activity. Exposure to 0.75, 3.0, or 10 ppm O_3 caused an early inhibition of enzyme activity. However, enzyme activity recovered by one day after exposure to O_3 . Neither early nor delayed effects on benzo(a)pyrene

hydroxylase activity were seen for NO₂, even at levels as high as 50 ppm.

5804 PERSISTENT BINDING OF A NEW REACTION PRODUCT OF THE CARCINOGEN *N*-HYDROXY-*N*-2-ACETYLAMINOFLUORENE WITH GUANINE IN RAT LIVER DNA *IN VIVO*. (E.) Kriek, E. (The Netherlands Cancer Inst., Amsterdam). *Cancer Res* 32(10):2042-2048, 1972.

The binding of 2-acetylaminofluorenyl residues (-AAF) to rat liver DNA *in vivo* was studied at different periods of time after administration of *N*-hydroxy-*N*-2-acetylaminofluorene-2'-³H. Liver DNA was hydrolyzed at pH 6 with a mixture of spleen phosphodiesterase and wheat germ acid phosphatase. The enzymatic digests were analyzed by Sephadex LH-20 column chromatography. Maximum levels of bound radioactivity were found in liver DNA at 16 to 18 hr following a single injection of *N*-hydroxy-*N*-2-acetylaminofluorene-2'-³H. The major part (80%) of the bound radioactivity was identified as *N*-(deoxyguanosin-8-yl)-2-acetylaminofluorene (dGuo-AAF), which disappeared rapidly from DNA with a biological half-life of approximately seven days. A second product, however, constituting 20% of the bound radioactivity, remained associated with DNA for periods of up to 8 wk after injection. Unlike dGuo-AAF, the minor product was not deacetylated by the action of 0.1 N NaOH or 0.1 N HCl at 75 C for 2 hr. The persistent -AAF residue was not detected in rRNA and tRNA from rat liver. The minor product with chemical and chromatographic properties similar to those of the persistent -AAF moiety *in vivo* was isolated from ¹⁴C-labeled DNA, which had been reacted with *N*-acetoxy-*N*-2-acetylaminofluorene-2'-³H *in vitro*. The ³H:¹⁴C ratio of this product was identical to the theoretical ³H:¹⁴C ratio, which was calculated for the reaction product dGuo-AAF, thus indicating that the persistent -AAF moiety in DNA is also bound to guanine. Persistent binding of radioactivity to rat liver DNA *in vivo* was also observed following a single injection of 2-acetylaminofluorene-9-¹⁴C-2'-³H. Previous reports that 70% of the total carcinogen bound to DNA at 24 hr had lost the *N*-acetyl group were confirmed. Approximately 20% of bound -AAF at 24 hr (5% of total carcinogen) remained associated with DNA at 4 wk after injection. The ³H:¹⁴C ratio of DNA at 4 wk was identical to the ³H:¹⁴C ratio of the isolated reaction product dGuo-AAF, indicating that there are no persistent 2-amino-fluorene residues. Administration of 2-acetylaminofluorene-9-¹⁴C-2'-³H resulted in 53% exchange of *N*-acetyl groups, but injection of *N*-hydroxy-*N*-2-acetylaminofluorene-9-¹⁴C-2'-³H did not result in significant exchange of the *N*-acetyl group.

5805 OBSERVATIONS ON THE EFFECT OF THYMECTOMY ON CHEMICAL CARCINOGENESIS IN THE HAMSTER CHEEK POUCH. (E.) Polliack, A. (Hadassah U. Hosp., Hebrew U.-Hadassah Med. School, Jerusalem, Israel),

I. S. Levi and R. Pfefferman. *Br J Cancer* 26(5): 368-377, 1972.

The effects of thymectomy and sham operation on 9,10-dimethyl-1,2-benzanthracene (DMBA) induced tumors of the hamster cheek pouch were studied in Syrian golden hamsters. The incidence of carcinomata and papillomata with intra-epithelial carcinoma (atypical papillomata) in these animals was compared with that in control animals treated with DMBA alone, without surgical intervention. In 32 non-operated control animals, the average tumor yield after 12 weeks' DMBA application was 2.13 carcinomata and 1.22 atypical papillomata per treated pouch. In 14 animals thymectomized at the age of two weeks, the tumor yield was 0.21 and 0.36, resp., and in ten animals thymectomized when adult, it was 0 and 0.1 resp. In nine animals sham operated on at the age of two weeks, an average of 1.56 carcinomata and 1.22 atypical papillomata were found, but in 13 animals which were sham operated when adult, the tumor yield was 0.54 and 0.15 per treated pouch, resp. The results suggest that the time of thymectomy in relation to DMBA treatment may be of importance and that thymectomy, when performed in 2-week old hamsters, inhibits DMBA tumorigenesis. The major effect of thymectomy performed in adult hamsters appears to be related to stress following surgery.

5806 INCREASED CYCLIC AMP LEVELS IN MALIGNANT HEPATIC NODULES OF ETHIONINE TREATED RATS. (E.) Chayoth, R. (U. Pittsburgh Sch. Med., Pa.), S. Epstein and J. B. Field. *Biochem Biophys Res Commun* 49(6):1662-1670, 1972.

Cyclic AMP levels were measured *in vivo* and *in vitro* in uninvolved liver, benign and malignant hepatic nodules of ethionine treated rats. The *in vivo* cyclic AMP concentration of 5.0 ± 0.5 nmoles/gm protein in malignant nodules was twice that in benign nodules and uninvolved liver. Values in tissue slices after sacrifice of anesthetized animals were identical to the *in vivo* levels. Cyclic AMP levels were higher in animals sacrificed by decapitation, but were not influenced by 20 minutes incubation. Concentrations in malignant nodules still exceeded those in other two tissues. The increased cyclic AMP concentrations in malignant nodules persisted whether the data was expressed on the basis of wet weight, protein or DNA.

5807 DETECTION OF THE PRINCIPAL PROTEIN TARGET OF A HEPATIC CARCINOGEN. (E.) Sami, B. P. (Inst. Cancer Res., Fox Chase, Philadelphia, Pa.), D. M. Mott, S. M. Szajman and S. Sorof. *Biochem Biophys Res Commun* 49(6):1598-1604, 1972.

Antiserum was prepared against the principal liver protein conjugate of the hepatic carcinogen, 3'-methyl-4-dimethylaminoazobenzene. One precipitin band was obtained when the antiserum reacted with the purified conjugate in double immunodiffusion gel analysis. The same anti-serum detected two proteins

in rat liver cytosol. Of these two proteins, one was immunoreactively identical to the purified antigen; in contrast, the other protein was only partly identical to it. Absorption of the antiserum with rat kidney cytosol yielded specific antiserum that reacted only with the protein that was immunologically identical to the purified conjugate. That protein, detected in normal rat liver cytosol, is apparently the principal protein target of the azocarcinogens in liver carcinogenesis.

- 5808 THE FORMATION OF VARIANTS WITH A REVERSION OF PROPERTIES OF TRANSFORMED CELLS. VII. *IN VITRO* LIMITED LIFE SPAN OF VARIANTS ISOLATED FROM TUMORS. (E.) Rabinowitz, Z. (Weizmann Inst. Sci., Rehovot, Israel) and L. Sachs. *Int J Cancer* 10(3):607-612, 1972.

Tumors were induced in hamsters following the s.c. inoculation of hamster embryo cells transformed *in vitro* by dimethylnitrosamine (DMNA). Cultures which were subsequently established from these tumor cells showed morphological and growth properties which differed from the original DMNA-transformed cell lines. These revertant cultures had a decreased saturation density and showed contact inhibition of cell replication. Revertant cells were able to form colonies on glutaraldehyde-fixed normal cells (unlike the original lines) and showed a decreased cloning efficiency on feeder layers and in soft agar. Like variants from tumors induced by polyoma virus-transformed cells, the revertant lines showed a higher tumor formation following s.c. inoculation into adult hamsters than did the original DMNA-transformed lines. Most (82-89%) of the variant colonies from tumors produced by DMNA-transformed cells exhibited a finite *in vitro* life span as compared to only 4% of the variant colonies from tumors produced by polyoma-transformed cells. Sixteen to 18% of the variant colonies isolated from DMNA-transformed cell tumors re-reverted to a transformed state as evidenced by re-establishment of a high saturation density and increased cloning efficiency on feeder layers and in soft agar.

- 5809 THE LEVELS OF SOME TRACE ELEMENTS IN TISSUES OF ANIMALS IN THE PROCESS OF THEIR SENSITIZATION TO METHYLCHOLANTHRENE. (Rus.) Kozhevnikova, E. P. (Orenburg Med. Inst., USSR). *Patol Fiziol Eksp Ter* 16(4):32-36, 1972.

CC57 mice received 0.2 mg methylcholanthrene into the right kidney; the same carcinogen in a benzene solution was brushed on the interscapular skin of these mice two months later. A control group of mice received the same dose of methylcholanthrene into the right kidney but did not receive the skin application. Trace elements in various tissues were determined by a spectral emission method four and six months after the first administration of the carcinogen and before the onset of morphological alterations associated with malig-

nant neoplasia. Zinc content in the kidney of experimental mice was significantly higher than that of controls four months after treatment. This difference disappeared by six months. Zinc tissue content for liver, spleen and skeletal muscle was comparable for both groups four months and six months after treatment. Copper content was higher in the spleen and lower in the skeletal muscle tissue of experimental mice at six months after treatment. No significant differences in manganese levels were found in the two groups of mice. In comparison with intact mice, zinc and copper levels were higher for both groups for all tissues studied, whereas manganese content was increased only in the kidney.

- 5810 TYPE C VIRUS FROM CELL CULTURES OF CHEMICALLY INDUCED RAT HEPATOMAS. (E.) Weinstein, I. B. (Columbia U. Coll. Physicians Surgeons, New York, N.Y.), R. Gebert, U. C. Stadler, J. M. Orenstein and R. Axel. *Science* 178(4065):1098-1100, 1972.

Evidence has been obtained for C-type virus production in cultures of various chemically induced rat hepatoma cell lines. Sucrose density centrifugation of medium from ³H-uridine prelabeled hepatoma cells consistently revealed a band of radioactivity at a density of 1.16 gm/cm³. Virus yield was markedly enhanced when the cells were first treated with bromodeoxyuridine followed by dimethyl sulfoxide. Electron microscopic observation of rat hepatoma cells revealed characteristic C-type particles associated with the plasma membrane. DNA polymerase assays suggested that the DNA polymerase associated with the C-type particles was deficient in reverse transcriptase activity. These results thus raise the possibility that activation of C-type viruses may play a role in the chemical induction of rat hepatomas.

- 5811 RESPONSE OF LYMPHOCYTES IN CHRONIC LYMPHOCYTIC LEUKAEMIA TO PLANT MITOGENS. (E.) Smith, J. L. (Dept. Med., U. Cambridge, England), D. C. Cowling and C. R. Barker. *Lancet* (7744):229-233, 1972.

Lymphocytes from 13 patients with chronic lymphocytic leukemia (CLL) were treated with each of three plant mitogens: phytohemagglutinin (PHA), pokeweed mitogen (PWM) or concanavalin A (Con A). Stimulation of CLL lymphocytes (and of normal cells as controls) by the three agents was measured by observing uptake of ³H-thymidine by treated cells. The reaction of CLL cells to PWM was of special interest in view of the theory that CLL arises from B cells, which are transformed by PWM. PHA caused maximal transformation of normal cells (a mean of 69% of cells in cultures were transformed by PHA); Con A caused a mean of 47% transformed cells and PWM caused a mean of 25% transformed cells. Lymphocytes from CLL donors showed markedly impaired responses to all three mitogens. One patient

with a high peripheral-blood lymphocyte-count gave a moderate response to Con A. It was suggested that leukemic cells may originate from B-cells, but that the cells are defective in that their recognition sites for PWM are altered or blocked.

- 5861 UNSCHEDULED DNA SYNTHESIS IN SOME SPONTANEOUS HUMAN TUMORS. (E.) Norman, A. (UCLA Sch. Med., Los Angeles, Calif.), R. E. Ottoman, P. Chan and I. Klisak. *Mutat Res* 15(3):358-360, 1972.

Seventeen histologically identified spontaneous human tumors were studied to determine whether or not they had the ability to undergo unscheduled DNA synthesis (DNA repair) following exposure to UV irradiation. Single cell suspensions of ovarian, endometrial, cervical, breast, colonic, and oral cancers obtained surgically were first exposed to UV light and then grown for a period in medium containing ^3H -thymidine. The extent of thymidine incorporation into DNA was determined by autoradiography. All of the tumor samples exhibited unscheduled DNA synthesis. The median grain counts over the nuclei of irradiated samples were at least five times those over the nuclei of the unirradiated controls. It was thus concluded that the mutations which occur in xeroderma pigmentosum cells, and which result in a severely depressed ability to undergo DNA repair, are not commonly associated with spontaneous tumors in man.

- 5862 EXAMINATION OF THE CARCINOGENIC AND COCARCINOGENIC EFFECTS OF GRENZ RADIATION. (E.) Epstein, J. H. (U. California Sch. Med., San Francisco). *Cancer Res* 32(12):2625-2629, 1972.

The effects of the chemical carcinogen 7,12-dimethylbenz(a)anthracene (DMBA) on long-wavelength ionizing radiation (grenz ray)-induced carcinogenesis in the skin of hairless mice were examined. The hairless mice were divided into four groups. In Group I (35 mice), the back of each mouse received a single application of acetone. Four weeks later, the backs of these animals were exposed to 100 R from a grenz ray source three times a week for 4.5 months and five times a week for seven months (a total of 20,500 R). In Group II (32 mice), the back of each mouse received a single 100- μg application of DMBA followed by irradiation as in Group I. The 25 Group III mice received the DMBA application as in Group II but no grenz ray exposures. The 41 Group IV mice received the acetone application but no irradiation. A single application of DMBA four weeks before the initiation of the grenz ray exposures resulted in a significant acceleration of tumor growth and an increased incidence of deeply invading cancers. Over a 12 month period 7 of 32 surviving Group I mice developed tumors; 18 of 28 Group II surviving mice developed tumors; 9 of 23 Group III surviving mice developed tumors and none of 32 surviving Group IV mice developed tumors. These findings demonstrate the influence of 7,12-dimethylbenz(a)anthracene on ultraviolet-induced cancer formation and confirm the additive effects of physical and chemical carcinogenic stimuli.

- 5863 THE REJOINING OF X-RAY-INDUCED DNA STRAND BREAKS IN NUCLEI ISOLATED FROM EHRLICH ASCITES TUMOR CELLS. (E.) Matsudaira, H. (Natl.

Inst. Radiol. Sci., Chiba, Japan) and I. Furuno. *Biochim Biophys Acta* 272(2):202-211, 1972.

Ehrlich ascites tumor cells from albino ddN mice were irradiated (340 R/min for 5 min) to induce single-stranded DNA breaks. After irradiation, isolated nuclei were incubated with cytoplasmic supernatants prepared from unirradiated Ehrlich cells and supplemented with ATP, NAD or NMN and sodium 3-phosphoglycerate. Other irradiated nuclei were incubated under similar conditions but in a solution containing bovine plasma albumin. Nuclear suspensions in cytoplasmic supernatants or bovine plasma-containing solution were subjected to sedimentation through alkaline sucrose gradients to observe the rejoining of X-ray induced DNS breaks. Incubation of DNA with cytoplasmic supernatant supplemented with ATP, NAD and 3-phosphoglycerate produced optimal rejoining. No rejoining was observed following incubation without cytoplasmic supernatant. Bovine plasma albumin was ineffective even in the presence of ATP, NAD and 3-phosphoglycerate, or when supplemented with pyruvate kinase and phosphoenolpyruvate. Possible mechanisms, including polynucleotide ligase reaction, underlying the rejoining of X-ray induced single-strand breaks are discussed.

- 5864 IMMUNE CYTOLYSIS AND X IRRADIATION: INDEPENDENT LETHAL ACTION IN CHINESE HAMSTER CELLS IN VITRO. (E.) Shipley, W. U. (Nat Cancer Inst., Bethesda, Md.). *J Nat Cancer Inst* 48(3):651-655, 1972.

Chinese hamster lung cells (CHL) in culture were exposed to 600 rads X-irradiation before and after addition of rabbit hyperimmune antiserum prepared against whole CHL cells. The extent of complement-mediated cytolysis in CHL pretreated with radiation, and in CHL irradiated after pretreatment with antiserum, was measured by the loss of colony-forming ability. The anti-serum survival curve (single cell surviving fraction vs. antiserum concentration) for cells surviving irradiation pretreatment was similar to that for unirradiated cells. Moreover, the X-ray survival curve for cells treated with antiserum was identical to that for cells not exposed to antiserum. It was concluded that there is no interaction between cytolysis by X-ray and cytolysis by immune serum.

- 5876 RNA-DEPENDENT DNA POLYMERASE ACTIVITY OF RNA TUMOR VIRUSES: II. DIRECTING INFLUENCE OF RNA IN THE REACTION. (E.) Leis, J. P. (Albert Einstein Coll. Med., Bronx, N.Y.) and J. Hurwitz. *J Virol* 9(1):130-142, 1972.

The role of RNA in DNA synthesis catalyzed by the purified DNA polymerase from avian myeloblastosis virus (AMV) was studied. Heat inactivation studies with AMV polymerase showed that polymerase activity with either DNA or RNA primers was inactivated at the same rate, indicating that one enzyme was responsible for both activities. Synthesis of DNA from an AMV RNA template by an AMV polymerase preparation containing no detectable ribonuclease activity (pII) required Mg^{++} , sulfhydryl reagents, and all four deoxyribonucleotide triphosphates. Activity showed a broad pH range (7.8-9.0), with a maximum at pH 8.2. AMV polymerase pII also directed DNA synthesis from RNA templates isolated from Rous sarcoma virus, Rauscher leukemia virus, phages f2, MS2 and Q β , bulk *E. coli* tRNA, and the synthetic homopolymer poly(A).poly(U). From 30 to 75% of the template activity of RSV and AMV RNA remained after heating at 80°C in buffer of low ionic strength. Incorporation experiments showed that only a limited amount of deoxynucleotide (equivalent to 3% of the added RNA primer) was incorporated into newly synthesized DNA. The single-stranded regions of AMV RNA were essential for template activity. Examination of the product of the AMV DNA polymerase and AMV RNA by various chemical and enzymatic methods identified it as DNA. It sedimented in alkaline sucrose gradients at 6 to 7S. The immediate polymerase product was identified as an RNA-DNA hybrid linked by covalent bonding, on the basis of the banding pattern in neutral sucrose gradients, digestion patterns with *Neurospora* or mung bean I nucleases, and analysis by Cs_2SO_4 equilibrium density gradient centrifugation. Deoxynucleotide incorporation occurred at the 3'-OH end of a poly d(AT) copolymer primer strand.

- 5877 TRANSFORMATION OF RHESUS FORESKIN CELLS BY MASON-PFIZER MONKEY VIRUS. (E.) Pienta, R. J. (Litton Bionetics, Bethesda, Md.), D. L. Fine, T. Hurt, C. K. Smith, J. C. Landon and H. C. Chopra. *J Nat Cancer Inst* 48(6):1913-1917, 1972.

Continuous lines of rhesus foreskin cells (rhfs-1 and rhfs-2) were infected with Mason-Pfizer monkey virus (M-PMV). Transformed cells were detected by their ability to grow in suspension when inoculated into semisolid agar medium. Further evidence for *in vitro* transformation by M-PMV was loss of contact inhibition on continued culture and the ability to grow in factor-free medium (Dulbecco's modified medium containing 10% agamma bovine serum previously heated at 70°C for 30-45 min). Transformed colonies showed altered morphology and contained both multinucleated and giant cells. The cells released virus as determined by electron microscopy and the ability to induce cytopathic effects in rhfs-2 cells. Tumorigenicity of transformed cells was shown by the ability to form palpable tumors at the site of inoculation within one wk following s.c. injection of 2×10^6 cells into newborn rhesus monkeys.

- 5878 SIALYL TRANSFERASE ACTIVITY IN NORMAL AND RNA- AND DNA-VIRUS TRANSFORMED CELLS UTILIZING DESIALYZED, TRYPSINIZED CELL PLASMA MEMBRANE EXTERNAL SURFACE GLYCOPROTEINS AS EXOGENOUS ACCEPTORS. (E.) Bosman, H. B. (U. Rochester Sch. Med. Dent., N.Y.). *Biochem Biophys Res Commun* 49(5):1256-1262, 1972.

An acceptor fraction of 3T3, PY-3T3, MSV-3T3, or RSV-3T3 cells was prepared by incubation of the whole cells with neuraminidase followed by trypsin digestion. Using this dialyzed, trypsinized acceptor fraction and detergent homogenates of the cell lines, the virally transformed cells were found to have 1.5 to 6.1 times as much sialyl transferase activity with CMP-NANA- ^{14}C as substrate than the 3T3 cells. Up to 30% of the sialyl transferase activity was expressible on the external plasma membrane of the cells. The acceptor fractions of the transformed cells contained about 1.5 times as many sites for transfer of NANA on a mg protein basis as did the 3T3 cells. By use of a trypsin treated, but not neuraminidase treated, cell acceptor fraction, it was determined that the virally transformed cells had higher amounts of incomplete glycoproteins on their surfaces that would function as acceptors in the sialyl transferase reaction, possibly because of higher levels of degradative enzymes which represent a form of sub-lethal autolysis in the transformed cells.

- 5879 ISOLATION OF AGMK CELLS PARTIALLY RESISTANT TO SV40: IDENTIFICATION OF THE RESISTANT STEP. (E.) Reznikoff, C. (Children's Hosp., Med. Ctr. Boston, Mass.), P. Tegtmeyer, C. Dohan, Jr. and J. F. Enders. *Proc Soc Exp Biol Med* 141(2):740-746, 1972.

African green monkey kidney cell (AGMK) monolayer cultures were infected with SV40. While the usual result was eventual complete cell lysis, some colonies of SV40-resistant cells survived as chronically SV40-infected cultures. Three such chronically infected lines were maintained in a culture medium containing rabbit anti-SV40 serum. From one of these lines three clones were established in the presence of anti-SV40 serum and designated SV40 resistant clones 1, 2 and 3. The three resistant clones were free of SV40 T antigen and produced no infectious SV40. Cells from these clones were not tumorigenic in the hamster cheek pouch. All clones showed partial resistance to reinfection with SV40 at high or low multiplicities of infection. One resistant clone resisted infection with SV40 virus but was susceptible to infection with isolated SV40 DNA.

- 5880 REVERSIBLE SUPPRESSION OF ALKALINE PHOSPHATASE IN HUMAN THYROID MEDULLARY CARCINOMA CELLS TRANSFORMED BY SV40. (E.) Wivel, N. A. (Natl. Cancer Inst., Bethesda, Md.) and P. M. Grimley. *Proc Soc Exp Biol Med* 139(2):627-630, 1972.

Primary cultures were initiated with explants of fresh surgical specimens of thyroid medullary carcinomas from two kindred males (56 and 26 yr) with multiple endocrine neoplasia. Some of the primary cultures were infected with and transformed by SV40. At selected intervals, alkaline phosphatase activity was determined by *in vitro* assay of infected and uninfected cultures. Enzyme activity was consistently demonstrated in serial subcultures of the two uninfected carcinoma lines. Enzyme activity in the SV40-transformed thyroid carcinoma lines was negligible. However, alkaline phosphatase activity in the transformed lines could be restored to preinfection levels by incubation of the cells with hydrocortisone (2.5 µg/ml). Enzyme induction occurred over a period of ten days after which time levels remained constant. No steroid induction of alkaline phosphatase was observed in uninfected thyroid carcinoma cells. Returning infected cells to medium without hydrocortisone caused enzyme activity to fall to pretreatment levels within 96 hr. Experiments using permissive African green monkey kidney cells infected with SV40 indicated that the production of virus was not associated with an increase in alkaline phosphatase activity.

5881. USE OF THE MOLECULAR HYBRIDIZATION TECHNIQUE *IN SITU* TO OBTAIN ELECTRON MICROSCOPIC EVIDENCE FOR VEGETATIVE DNA REPLICATION IN SHOPE VIRUS-INDUCED PAPILLOMAS OF THE COTTONTAIL RABBIT. (Fr.) Croissant, O. (Gustave-Roussy Inst., Villejuif, France), C. Dauguet, P. Jeanteur and G. Orth. *CR Acad Sci (Paris)* 274(4):614-617, 1972.

Electron microscope studies have shown evidence of vegetative replication of viral DNA and of its localization in skin papillomas induced in cottontail rabbits by Shope virus after *in situ* hybridization of viral DNA with tritiated complementary RNA. The molecular hybridization technique *in situ* furnishes autoradiographic evidence of repetitive nucleotide sequences in cytological sections. Papilloma sections were fixed, incubated with tritiated RNA complementary to viral DNA, washed, incubated with an RNase solution, and fixed with glutaraldehyde and osmium tetroxide. Ultrathin sections were mounted between histological slides which were kept for three months at 4 C in darkness, after which latent images were brought out by a gold stain and a developer. The preparations were examined by electron microscope and the labeling rate measured after three months exposure. Neither the thickness of the sections nor glutaraldehyde fixation interfered with the formation of RNA-DNA hybrids. The induction of vegetative replication of viral DNA was detected in the nuclei of cells in the lower third and middle of the *stratum granulosum*. Small numbers of silver grains in the labeled cells were observed in condensed peripheral and nucleolar chromatin or, more frequently, were dispersed in the nucleoplasm. The labeling rate increased with the migration of cells to the surface, reaching 100-350 grains per 10 µ² in the nuclei of cells above the *stratum granulosum*. The observations did not show whether vegetative replication took place preferentially in the nuclear membrane or the chromatin. A long latent period was detected between viral DNA

replication and the appearance of the first virions. Large amounts of free viral DNA were found in imperfectly keratinized cells which suggest that an important fraction of viral DNA is destroyed in the last stage of keratinization.

5882 FATE OF VIRUS DNA IN THE ABORTIVE INFECTION OF HUMAN LYMPHOID CELL LINES BY EPSTEIN-BARR VIRUS. (E.) Jehn, U. (Karolinska Inst., Stockholm, Sweden), T. Lindahl and G. Klein. *J Gen Virol* 16(3):409-412, 1972.

The fate of ³H-prelabeled Epstein-Barr (EB) virus DNA was investigated after abortive superinfection of two different human lymphoid cell lines (Raji and NC37). At 40 hr after infection when "early antigen" was being expressed, the cells were lysed and the cellular distribution of radioactivity was determined. Approximately 50% of the total intracellular radioactivity was found in the nuclei. More than 50% of this ³H-labeled nuclear DNA was present in a DNase-sensitive form. Sucrose density and CsCl equilibrium density centrifugation studies showed that the labeled intranuclear DNA was undegraded, non-integrated EB virus DNA. These results therefore did not support the concept of covalent association between virus DNA and cellular DNA, and integration of virus DNA on a scale observed in other systems. It was also concluded that the observed expression of early virus functions 20 to 50 hr after superinfection of lymphoid cells may depend on transcription of the incoming EB virus DNA.

5883 DETECTION OF LEUKEMIA-LIKE VIRUSES A AND B IN HEp-2 CELL CULTURES OF A STABLE CELL LINE OF HUMAN LARYNGEAL CANCER. (Rus.) Il'in, K. V. (N. F. Gamaleya Inst. Epidemiol. Microbiol., Acad. Med. Sci. USSR, Moscow), A. F. Bykovskii and Zh. Zh. Spure. *Biull Eksp Biol Med* 73(2):86-89, 1972.

Viruses were detected in the cultures of transplantable HEp-2 cells from human laryngeal cancer. Trypsinized cultures of rabbit kidney tissue and human 4-month-old embryonal cells were incubated at 37 C for 7-10 days in a concentration of 50,000 cells/ml in a nutrient medium containing 10% Hank's solution, 0.5% lactalbumin hydrolysate, and 20% bovine serum. HEp-2 culture incubated in a similar medium was filtered and the cell-free filtrate inoculated on monolayers of rabbit kidney cells or human embryonal cells at 37 C for 4 hr, after which nutrient medium was added for culture growth. Twenty-five days post-infection the liquid phase of this culture, obtained by filtration through a G-4 glass plate, was subjected to centrifugation. Aliquots of the sediment in combination with Freund's adjuvant were inoculated to rabbits (intrapopliteal lymph node) for immunization. Rabbit serum obtained 16 days after inoculation was added to intact human embryo cells and the latter subjected to indirect fluorescence antibody studies 30 days later. Monolayer cultures were subjected to electron microscopy after 20 days of growth. Type A and B

viruses were detected in HE_p-2 cell cultures and in the infected rabbit kidney and human embryo cells. The viruses were capable of showing productive cycle in cultures of rabbit kidney cells and human embryonal cells, but did not cause cytopathological and transformational changes in the cells. Virus nucleoids of type A (diameter 500-550 Å) were localized in the cytoplasm of interphase and dividing cells. The external membrane of the virion type A (diameter 850-950 Å) was formed from elements of the cytoplasmic membrane. The membrane of the nucleoid of the virus type B (diameter 400-450 Å) is formed from the membrane of the endoplasmic reticulum. The external membrane of the virion of type B (diameter 900-950 Å) is formed from the cytoplasmic membrane. The cytoplasm of infected human embryonal cells showed antibodies in response to immune serum, indicating the presence of a virus.

- 5884 IMMUNOLOGICAL CROSS REACTIONS BETWEEN VIRUS PRODUCING AND NONVIRUS PRODUCING MAMMARY CARCINOMAS IN MICE. (Ger.) Zotter, St. (Med. Acad. Carl Gustav Carus, Dresden, East Germany), C. Kemmer, M. Müller and B. Micheel. *Arch Geschwulstforsch* 40(1):23-34, 1972.

Immunological cross reactions are described between mammary tumor virus (MTV)-producing mammary tumors (MT) and an apparently virus-free MT, which indicate the existence of a virus-coded cell antigen in these tumors. The studies were carried out with four MTs from syngeneic CBA/B1n mice immunized with a purified MTV preparation. Two carcinomas (MT 4814/24 and MT 8020/15) were virus-free, virus production could not be definitely demonstrated in a third carcinoma (MT 9915/5), and one which had been transformed since the sixth generation and originated from a virus-containing tumor (MT 7782/11) had become virus-free. The membrane immune fluorescence test was positive for tumors MT 4814 and 8020 and negative for MT 9915 and 7782. During the examination of the cell suspensions under the electron microscope, budding and mature MTV particles were seen in MT 4814 and 8020, following incubation with syngenic hyperimmune sera. In addition to virus labeling, deposits of ferritin complexes were seen in the virus-containing tumors; MT 9915 cell membrane was similarly marked. Normal CBA serum showed no

membrane deposits of this nature, the ferritin complexes occurring in random fashion with no relationship to the cell membrane. Ferritin labeling was not seen in the transformed MT 7782. Growth of MT 8020 and MT 9915 was significantly inhibited by mixtures with hyperimmunized spleen and peritoneal cells from CBA female mice, whereas growth of MT 7782 was not affected by these cells.

- 5885 TYPE C VIRUS PARTICLES IN CELL-FREE-INDUCED SARCOMAS OF SYRIAN HAMSTERS. (Ger.) Graffi, I. (Central Inst. Cancer Res., Berlin, East Germany), E. Bender, T. Schramm and A. Graffi. *Arch Geschwulstforsch* 39(4):281-292, 1972.

Electron microscopic investigations of virus particles in cell-free filtrate-induced hamster sarcomas are presented. Most of the sarcomas (fibrosarcomas or spindle cell sarcomas) induced by the cell-free filtrates from hamster skin epitheliomas developed at the inoculation site in the subcutis of the animal's back or side trunk. Virus particles at different stages of maturity were observed in various of these sarcomas. All virus particles exhibited a common basic structure featuring a well-defined envelope and a nucleoid with a sharply delineated membrane. Sometimes the particles appeared somewhat deformed indicating degenerative alterations. The total particle diameter averaged 80-100 nm and that of the nucleoid ranged between 55 and 60 nm. Particle maturity could be evaluated according to the electron optical density of the nucleoid. Virus particles occurred in both intercellular spaces and cytoplasm but were never detected in the nucleus of the sarcomatous cells. Their structural features corresponded to those of C-type viruses indicating that cell-free filtrate induction of sarcoma occurs through typical C-particle viruses.

- 5886 GAZDAR STRAIN OF MURINE SARCOMA VIRUS. BIOLOGIC AND ANTIGENIC INTERACTIONS WITH THE HETEROLOGOUS HAMSTER HOST. (E.) Sarma, P. S. (Nat'l. Cancer Inst., Bethesda, Md.), A. F. Gazdar, H. C. Turner and P. D. Kunchorn. *Proc Soc Exp Biol Med* 140(3):928-933, 1972.

Newborn hamsters were inoculated s.c. with Gazdar strain murine sarcoma virus (Gz-MSV). Undifferentiated, transplantable sarcomas developed at the site of inoculation by 21-45 days. Partially purified concentrates of primary and transplanted Gz-MSV hamster tumors were free of demonstrable infectious MSV or MuLV as tested by inoculation into newborn BALB/c and NIH Swiss mice and by a tissue culture complement-fixing antigen induction test, the COMUL test *in vitro* in cultures of NIH Swiss MEF and Syrian hamster embryo fibroblasts. Electron microscopic examination of primary and tissue culture cell lines derived from transplanted tumors showed mature and budding C-type virus particles. Gz-MSV-induced hamster tumors contained high titers of the MuLV species-specific group specific (gs) antigen. Hamsters with primary or transplanted Gz-MSV tumors developed complement fixing (CF) serum antibodies against the gs antigens of the mouse C-type viruses present in Moloney MSV rat tumors and in Rauscher leukemia virus preparations. These sera also reacted with hamster and mouse preparations of homologous Gz-MSV, but did not react against preparations of SV40 or polyoma virus-induced hamster tumors. The gs antisera from Gz-MSV tumor-bearing hamsters were as efficient as Moloney MSV tumor-bearing rat sera in detecting murine leukemia gs viral antigens and infectious virus in the COMUL test.

- 5887 PARTIALLY DOUBLE-STRANDED RNA IN MOUSE SPLEEN CELLS: THE EFFECT OF RAUSCHER

VIRUS INFECTION. (E.) Kissel'ov, F. L. (USSR Acad. Med. Sci., Moscow), L. A. Semjonova, I. S. Irlin and G. G. Shatalova. *Arch Gesamte Virusforsch* 36:265-274, 1972.

Rauscher leukemia virus (RLV)-containing plasma from leukemic BALB/c mice was injected i.v. into mice. RNA was isolated from spleens of recipients, fractionated in sucrose gradients and further fractionated on cellulose columns. A partially double-stranded RNA fraction (designated RNA-x) which eluted with STE (NaCl, Tris-HCl buffer, EDTA) was detected. RNA-x consisted of a population of heterogeneous molecules. It had a more ordered structure than typical single-stranded RNAs as indicated by its lower buoyant density. RNA-x appeared to be synthesized in infected cells. When mice were injected with RLV preparations on different multiplicities of infection, it was found that mice given high multiplicities produced large amounts of RNA-x. In C⁵⁷/BL mice insensitive to RLV, the amount of RNA-x after infection did not exceed the normal level. These results suggest that RNA-x synthesis is specific to mice undergoing RLV oncogenesis.

5888 THE LYMPHOCYTE RESPONSE TO A PRIMARY VIRAL NEOPLASM (MSV) THROUGH ITS ENTIRE COURSE IN BALB/c MICE. (E.) Lamon, E. W. (Dept. Tumor Biol., Karolinska Inst., Stockholm, Sweden), H. M. Skurzak and E. Klein. *Int J Cancer* 10(3):581-588, 1972.

BALB/c mice injected with Moloney sarcoma virus (MSV) developed tumors within 5-8 days which usually completely regressed by day 20-25. Maximal tumor size was around day 15. Lymphocytes from these animals were examined for activity against target cells bearing the Moloney leukemia virus (MLV) associated cell surface antigen at 2- to 5-day intervals for 30 days. Significantly cytotoxic lymphocytes were obtained from animals which had developed no palpable tumor as early as two days after infection and from animals in which tumors had completely regressed. The least active lymphocytes were from tumor-bearing animals. The cytotoxicity of the active lymphocytes was demonstrated to be antigen-specific by testing also against cells which were MLV-negative.

5889 INDUCTION OF MOUSE TUMOURS BY MEANS OF VIROGENIC RAT TUMOUR CELLS CONTAINING NON-INFECTIOUS ROUS SARCOMA VIRUS GENOME. (E.) Bubenik, J. (Inst. Exp. Biol. Genetics, Czechoslovak Acad. Sci., Prague), M. Baresova, V. Sovova, H. Sainerova and L. Donner. *Folia Biol (Praha)* 18(2):154-159, 1972.

The RSL rat tumor, induced by Schmidt-Ruppin Rous sarcoma virus, was established in tissue culture. Cultured RSL cells produced sarcomas on i.m. or s.c. injection into C57BL/10Sn mice, though neither cell-free material nor tissue culture fluid from RSL cultures produced tumors in mice. The sarcomas produced by RSL cells in mice were designated RSM.

RSM could be passaged in C57BL/10Sn mice but not in rats of the strain in which RSL was originally induced. *In vitro*, RSM grew more slowly than RSL; further, RSL contained a group-specific avian leukovirus antigen while RSM did not. RSM tumor cells were karyologically mouse cells. RSL cells, transplanted in chickens, gave rise to sarcomas which produced Rous sarcoma virus. RSM cells were not sarcomagenic chickens. Neither cell-free material nor culture fluid from RSL or RSM cells was sarcomagenic in chickens.

5890 ULTRASTRUCTURAL CHARACTERIZATION OF HAMSTER CELLS TRANSFORMED FOLLOWING EXPOSURE TO ULTRAVIOLET-IRRADIATED HERPES SIMPLEX VIRUS TYPE 2: (E.) Glaser, R. (M. S. Hershey Med. Ctr., Pennsylvania State U.), R. G. Duff and F. Rapp. *Cancer Res* 32(12):2803-2806, 1972.

Hamster embryo fibroblasts were transformed *in vitro* following exposure to UV-irradiated HSV-2. When cells from these cultures were inoculated into newborn hamsters, solid tumors developed. Continuous cell cultures of the tumor specimens were established. The virus-transformed cells, the solid tumors, and the tumor cell cultures were examined by electron microscopy. The transformed cultures and tumors contained cells with nuclei in which the chromatin had become condensed and marginated; this picture resembled the cytopathology induced during lytic infection by herpes simplex virus. These abnormalities were observed in some cell culture lines established from the tumors. Virus-like particles, similar in size and morphology to nonenveloped herpesvirus, were found in the nuclei of a small number of degenerating cells in some of the specimens examined.

5891 EXPERIMENTAL MALIGNANT TUMORS FROM RETINAL PIGMENT EPITHELIUM. (E.) Albert, D. M. (Yale U. Sch. Med., New Haven, Conn.), M. O. M. Tso and A. S. Rabson. *Arch Ophthalmol* 88(1):70-74, 1972.

Retinal pigment epithelium (RPE) from hamster eye was infected with simian vacuolating virus 40 and cultured. Transformed infected RPE tissue was injected s.c. into irradiated (400 roentgens) hamsters. Three wk later, all injected animals had developed malignant injection site tumors. The tumors metastasized to various sites, including lung, liver and brain, and killed their hosts by eight wk postinjection. The tumors were made up of spindle-shaped and epithelioid cells, and resembled human RPE tumors.

5892 DEGRADATION OF DNA RNA HYBRIDS BY RIBONUCLEASE H AND DNA POLYMERASES OF CELLULAR AND VIRAL ORIGIN. (E.) Keller, W. (Cold Spring Harbor Lab., N.Y.) and R. Crouch. *Proc Nat Acad Sci USA* 69(11):3360-3364, 1972.

Ribonuclease H (RNase H) from human KB cells and

from chick embryo cells, calf thymus cells, avian myeloblastosis virus (AMV) and Rous-associated virus was used to break down the synthetic DNA-RNA hybrid poly(dT)•((³²P)rA). In breaking down the hybrid, KB cell RNase H produced oligonucleotide and mononucleotide fragments. RNase H from KB cells and from AMV degraded only the RNA strand of the DNA-RNA hybrid, while exonuclease III and certain cellular DNA polymerases attacked both DNA and RNA. Oligonucleotides generated by cellular and viral RNase H terminated with a 5'-phosphate. Cellular RNase H was thought to be an endonuclease, while the viral enzyme acted as an exonuclease. Viral DNA polymerase and RNase H copurified through all separation steps. Therefore, RNase H activity is an intrinsic part of the viral DNA polymerase.

- 5893 INHIBITION BY α -AMANITIN OF SIMIAN VIRUS 40-SPECIFIC RIBONUCLEIC ACID SYNTHESIS IN NUCLEI OF INFECTED MONKEY CELLS. (E.) Jackson, A. H. (Cold Spring Harbor Lab., N.Y.) and B. Sugden. *J Virol* 10(5):1086-1089, 1972.

Experiments were conducted to determine which of the two major DNA-dependent RNA polymerases of mammalian cells is responsible for transcribing SV40 DNA. Nuclei isolated after 30 hr from lytically infected green monkey kidney cell cultures were assayed for RNA polymerase activity by determining the rate of ³H-UTP incorporation into acid insoluble material. Incorporation of radioactivity into SV40-specific RNA as determined by RNA-DNA hybridization studies was totally inhibited by α -amanitin. Since α -amanitin has been shown to have a selective inhibitory effect on mammalian RNA polymerase II, it was concluded that this enzyme probably is responsible for transcribing SV40-specific RNA in lytically infected cells. However, the possibility that RNA transcription was directed by an α -amanitin-sensitive viral-coded polymerase or by a viral modified host polymerase could not be excluded.

- 5894 MITOCHONDRIAL THYMIDINE-DEOXYURIDINE-PHOSPHORYLATING ACTIVITY AND THE REPLICATION OF MITOCHONDRIAL DNA. (E.) Kit, S. (Baylor Coll. Med., Houston, Texas) and Y. Minekawa. *Cancer Res* 32(11):2277-2288, 1972.

The replication of superhelical mitochondrial DNA was studied in SV40-transformed monkey, human and mouse cells, untransformed cells of these species; malignant cells and thymidine-kinase-deficient mouse cells. Superhelical mitochondrial DNA was extracted from ³H-thymidine-labeled cells by Hirt's procedure. ³H-thymidine incorporation by low-molecular wt Hirt supernatant DNA and by nuclear DNA was also studied. The different cell lines differed by no more than a factor of three in the amounts of ³H-thymidine their superhelical mitochondrial DNA incorporated. The radioactivity of this DNA varied only from 1,300-4,100 cpm/culture. However, the radioactivity of nuclear DNA varied from 21,000-6,200,000 cpm/culture, and the radioactivity of low-molecular wt DNA from 1,100

to 35,000 cpm/culture. Cycloheximide, an inhibitor of protein synthesis, markedly reduced labeling of nuclear and light-density Hirt supernatant DNA, but had little effect on labeling of mitochondrial DNA. Puromycin had a similar effect, while chlormaphenicol did not affect labeling of any DNA fractions. Thymidine-deoxyuridine-phosphorylating activity was detected in mitochondria of thymidine kinase-positive and thymidine kinase-deficient cell lines. Mitochondrial DNA apparently was not homologous in its sequence with SV40 DNA.

- 5895 BIOCHEMICAL METHOD FOR INSERTING NEW GENETIC INFORMATION INTO DNA OF SIMIAN VIRUS 40: CIRCULAR SV40 DNA MOLECULES CONTAINING LAMBDA PHAGE GENES AND THE GALACTOSE OPERON OF *ESCHERISCHIA COLI*. (E.) Jackson, D. A. (Stanford U. Med. Ctr., Calif.), R. H. Symons and P. Berg. *Proc Nat Acad Sci USA* 69(10):2904-2909, 1972.

Methods were developed for joining covalently any two DNA molecules. Using the method, circular dimers of SV40 DNA were constructed and a DNA segment containing λ phage genes and the galactose operon of *E. coli* was covalently integrated into the circular SV40 molecule. Circular SV40 DNA molecules were opened to linear duplexes by R₁ endonuclease cleaving. Oligo(dA) or -(dT) extensions were added to the 3'-hydroxyl termini of the DNA strands using the terminal deoxynucleotidyl transferase enzyme. Complementary homodeoxypolymeric extensions were added to the other DNA strand, and the two DNA molecules were annealed, forming a circular duplex. Finally, gaps in the molecular structure were filled with *E. coli* DNA polymerase and DNA ligase.

- 5896 STUDIES OF RETICULUM CELL SARCOMA IN HAMSTERS. (E.) Gerber, M. J. (Chicago Med. Sch., Ill.) and E. R. Brown. *Cancer Res* 32(10):2075-2081, 1972.

Tissue cultures were prepared from cells or ascites cells of a reticulum cell sarcoma of mice (RCS) by trypsinization of the tumor itself, by trypsinization of kidneys of tumor-bearing mice, or by suspension of ascites cells in culture medium. Cell-free filtrates from the RCS failed to induce tumors in X-irradiated or unirradiated hamsters. However, living cells from the three types of RCS tissue culture induced RCS in hamsters. No infectious murine leukemia virus (GC) was detected in these RCS tissue cultures. However, 36 of 60 mice injected with a mixed culture of tumor cells and mouse embryo cells demonstrated a leukemia comparable with the disease induced by GC virus. Thus RCS cells in culture are virogenic. Moreover, complement fixation tests with RCS cell and anti-GC sera showed that the former possessed murine leukemia virus soluble and membrane-associated antigens.

- 5897 HISTOCHEMICAL STUDY OF REDOX ENZYMES IN THE PROCESS OF VIRUS CARCINOGENESIS. (Rus.) Polukhina, M. A. (L. A. Tarasevich State Control Inst. Med. Biol. Prep., Moscow, USSR).

Biul Eksp Biol Med 73(3):78-80, 1972.

The state of redox enzymes related to glycolysis, Krebs cycle, and electron transport was studied histochemically, using tumors induced s.c. in hamsters by monkey adenovirus SA7(C8). Tumors were induced in all 158 newborn hamsters inoculated s.c. with 0.2 ml undiluted virus. The hamsters were killed 1-38 days after infection. NAD- and NADH diaphorases, succinate dehydrogenase, glucose 6 phosphate dehydrogenase, α -glycerophosphate, lactic, glutamic and isocitric acid dehydrogenases in the subcutaneous cellular tissues were studied. Tumor growth was accompanied by changes in the state of the redox enzymes in fibroblast cells as well as in tumor cells. These changes can be divided into three stages. The first stage (the first three days) is characterized by decreased enzyme activity in the fibroblast cells of the experimental hamsters. The second stage, corresponding to 5-20 days, is associated with increased activity of all enzymes except succinate dehydrogenase and isocitrate dehydrogenase and with changes in the form of "diphormasan" deposition in cells. These changes are probably due to the changes in the mitochondrial membranes. The third stage, corresponding to 19-21 days, is characterized by monomorphism of diphormasan deposition in the cells, increased glucose 6 phosphate dehydrogenase and lactate dehydrogenase and decreased NAD- and NADH-diaphorases. The changes in the enzyme activities in the second and third stages were characteristic of the biochemistry of tumor cells, irrespective of the type of carcinogenesis.

5898 MORPHOLOGICAL TRANSFORMATION OF HUMAN ASTROCYTES BY VISNA VIRUS WITH COMPLETE VIRUS PRODUCTION. (E.) Macintyre, E. H. (Dept. Biol. Sci., U. Denver, Colo.), C. J. Wintersgill and J. Thormar. *Nature New Biol* 237:111-113, 1972.

A comparative study was made of the effects of visna virus on sheep choroid plexus cells (SCP) and a permanent line of human astrocytes, 1181N1, derived from a highly malignant brain tumor. Visna-infected SCP cells were all dead by the tenth day postinfection. They produced virus at titers of $10^{6.5}$ TCID₅₀/0.1 ml cell-free supernatant and carried virus-specific cytoplasmic antigen. When grown in Eagle's minimal essential medium (MEM) supplemented with 10% lamb serum, visna-infected 1181N1 cells were morphologically transformed 12 days after infection. The cells produced virus at titers of $10^{2.7}$ TCID₅₀/0.1 ml cell-free supernatant and also carried the visna-specific antigen. Although the final morphological expression was the same for all 1181N1 cells, astrocytes grown in MEM supplemented with 10% fetal calf serum were not completely transformed until 29 days after infection. Transformed 1181N1 cells maintained the ability to produce virus even after 4.5 months *in vitro*.

5899 CYTOGENETIC CHARACTERISTICS OF TWO NEW TRANSPLANTABLE CELL LINES OF GRAY

HAMSTERS (*CRICETULUS MIGRATORIUS*) TRANSFORMED BY ROUS SARCOMA VIRUS. (Rus.) Markaryan, D. S. (Inst. Exp. Biol., Armenian SSR, Acad. Sci., Yerevan, USSR), D. M. Martirosyan and M. V. Avdzhian. *Biul Eksp Biol Med* 72(11):83-86, 1971.

A cytogenetic study was performed on two new Rous sarcoma virus-transformed transplantable hamster cell lines. XPO-1 culture was obtained from tumors induced by Rous sarcoma virus in 2-week-old gray hamsters after three s.c. inoculations of chick sarcoma cells. HET-Asa culture was obtained from the culture of gray hamster embryonal fibroblasts transformed by Rous sarcoma virus. Both cultures had undergone more than 100 passages prior to the time of study. Both cultures were characterized by the heteroploid karyotype, characteristic for transplantable cell cultures. There was a high incidence of dicentric chromosomes in both cultures: 30/100 cells in HET-Asa culture and 23/100 cells in XPO-1 culture. The dicentric chromosomes survived for as long as two months. There was also a high percentage of near- and pseudodiploid cells in both cultures: cells with 21-22-23 chromosomes were predominant and showed selective advantages in the given conditions over aneuploid cells with more chromosomes. Diploid, hypodiploid, and hyperdiploid cells often lacked the 8-10 chromosome group. The intense chromosomal aberrations in both cultures are perhaps related to metabolic anomalies or to the presence of some biologic agent in the cell cultures.

5900 AN OLIGONUCLEOTIDE AFFINITY COLUMN FOR RNA-DEPENDENT DNA POLYMERASE FROM RNA TUMOR VIRUSES. (E.) Gerwin, B. I. (Natl. Cancer Inst., Bethesda, Md.) and J. B. Milstien. *Proc Nat Acad Sci USA* 69(9):2599-2603, 1972.

Rauscher murine leukemia virus and human C-type virus from RD-114 cells were disrupted and the solubilized fractions containing polymerase activity were applied to (dT)₁₂₋₁₈-cellulose columns. RNA-dependent DNA polymerase of both viruses was recovered from the (dT)₁₂₋₁₈-cellulose columns. Uninfected 3T3FL cells showed no polymerase activity in (dT)₁₂₋₁₈-cellulose columns, while Moloney virus-infected 3T3FL cells demonstrated polymerase activity in the columns. This indicated the preference of viral as compared to cellular DNA polymerases for (dT)₁₂₋₁₈ as a primer.

5901 RNA TUMOR VIRUS DNA POLYMERASE: ACTIVITY WITH EXOGENOUS PRIMERS. (E.) Kiessling, A. A. (U. Washington Sch. Med., Seattle) and P. E. Neiman. *Biochim Biophys Acta* 272(2):147-155, 1972.

Studies were carried out *in vitro* to measure the primer preference of DNA polymerase activity released from detergent-treated virions of avian myeloblastosis virus (AMV) and Prague Rous sarcoma virus (PrRSV). Native DNA from avian leukemic myeloblasts had only a slight stimulatory effect on DNA synthesis by AMV or PrRSV DNA polymerase. Pretreatment with bovine pancreatic

deoxyribonuclease markedly enhanced the priming activity of myeloblast DNA. Maximally activated DNA, obtained following a 60 min incubation with bovine pancreatic ribonuclease, had a sedimentation velocity constant of 6S. Sonicated myeloblast DNA fragments did not stimulate DNA synthesis by virus polymerases, and pretreatment with micrococcal nuclease decreased the priming efficiency of myeloblast DNA. These findings suggest a specificity of the viral polymerases for 3'hydroxyl groups in the primer. The DNA product could not be separated from partially activated 15S DNA by sedimentation on velocity gradient even under alkaline conditions, indicating a covalent bond between primer and product. The maximum velocity of DNA synthesis was extrapolated from Lineweaver-Burke plots of the rate of DNA synthesis in the presence of increasing concentrations of maximally activated DNA primer. The values obtained were then compared with those for a variety of RNA and DNA primers as well as synthetic RNA-DNA hybrids. There appeared to be a preference for partially double stranded nucleic acids containing an excess of 3'hydroxyl groups.

RNA molecules synthesized late during productive infection in mouse cells was examined. The Py-specific RNA from whole cells, and from nuclear, cytoplasmic, and polyribosome fractions were compared with respect to sedimentation behavior (on sucrose gradients), electrophoretic mobility (on polyacrylamide gels), and base sequence homology (by competitive hybridization tests). Sedimentation and electrophoretic analysis revealed marked heterogeneity in PyRNA from all cell fractions. This heterogeneity and relative size distribution were essentially the same on dimethylsulfoxide- and on aqueous-sucrose gradients. The PyRNA from different regions of a sucrose gradient contained common sequences, as revealed by cross competition-hybridization experiments. However, the polyribosome-associated PyRNA was devoid of the >28 S species found in the other fractions. Thus, it appears that PyRNA, including RNA of apparent size in excess of one genome length, is synthesized in the nucleus and cleaved to smaller pieces in association with polyribosomes.

5902 INHIBITION OF HIPA PLASMACYTOMA CELL-FREE TRANSMISSION BY NORMAL SPLEEN OF BALB/c, DBA/2 AND C3H MICE. (E.) Pedio, G. (Inst. Path. Anat., U. Zurich, Switzerland) and J. R. Rüttner. *Int J Cancer* 8:497-502, 1971.

Cell-free extracts of the HIPA plasmacytoma were obtained by ultracentrifugation of tumor ascites from various strains of mouse; lethal doses of tumor cell ultracentrifugate were inoculated into ICR, C3H, BALB/c and DBA/2 mice one wk after i.p. inoculation of the mice with normal BALB/c mouse spleen homogenate. Seventy percent of mice given spleen homogenates survived the lethal dose of HIPA plasmacytoma ultracentrifugate. This protection was independent of the source of the HIPA tumor ultracentrifugate; ICR mice were equally protected by BALB/c spleen homogenates when HIPA ultracentrifugates came from ICR or BALB/c mice. Protection was maximal (75-100%) in ICR and C3H mice given spleen homogenates. DBA/2 mice and syngeneic BALB/c mice were protected, but the effect was weaker (50-57% protection) than in strains ICR and C3H. Spleen homogenates from DBA/2 and C3H mice had a protective effect comparable to that of BALB/c spleen homogenates. The factor responsible for protection was found in the sedimentable fraction of spleen homogenates centrifuged at 500 x g for 15 min and was destroyed by heat and freeze/thaw treatment. BALB/c spleen homogenate did not protect against cellular transplantation of HIPA plasmacytoma.

5903 THE PROCESSING OF POLYOMA VIRUS RNA SYNTHESIZED DURING PRODUCTIVE INFECTION IN MOUSE CELLS. (E.) Petric, M. (Dept. Microbiol., U. British Columbia, Vancouver, Canada) and J. B. Hudson. *Can J Biochem* 50(8):927-935, 1972.

The intracellular distribution of polyoma (Py) virus

5904 DIFFERENT NEOPLASTIC RESPONSE OF MICE AND RATS TO INFECTION BY MURINE SARCOMA VIRUS (MOLONEY). (E.) Kano-Tanaka, K. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan), T. O. Yoshida, T. Tanaka, K. Kojima and T. Hanaichi. *Gann* 63(4): 445-457, 1972.

The biologic activity of and the macroscopic, histologic and ultrastructural characteristics of the lesions induced by three lines of murine sarcoma virus (Moloney) (MSV-M) were compared. MSV-M was maintained by cell-free transmission of mouse tumors through newborn BALB/c mice (MSV-M stock line) and by cell transplants of an MSV-induced sarcoma through young BALB/c mice (MSV-sarcoma line). A third cell-free passage (MSV-rat line) was maintained in newborn WKA rats. All three virus lines were oncogenic in both BALB/c mice and WKA rats; however, the neoplastic response differed. MSV-M produced predominantly myosarcomas at the site of injection in mice but induced primarily osteosarcomas in rats. Occasionally, myosarcomas associated with bone tumors were observed in rats receiving mouse-derived virus. Mice and rats which survived for long periods rarely developed lymphoma. Mice which received rat-derived virus or received high passage mouse-derived virus frequently showed bone tissue hyperplasia adjacent to neoplastic lesions. In rats, cystic lesions were found in high incidence in lymph nodes. Rats were generally less sensitive to MSV-M tumor induction, requiring doses of inocula 10^4 times greater than those necessary to induce tumors in mice. Tumor incidence in rats receiving mouse-derived MSV increased with increasing passage, whereas that with rat-derived MSV showed little increase. Electron microscopic observation revealed C-type particles in tumor cells, spleen cells and megakaryocytes from spleen and bone marrow of both rats and mice. Rat bone tumor cells could be transplanted to WKA rats by cell-grafts only with difficulty, with successful transplants often regressing after

a short time. Tumors of other than bone origin were transplanted with somewhat more success.

5905 THE EFFECT OF NEURAMINIDASE ON THE AGGREGATION OF BHK 21 CELLS AND BHK21 CELLS TRANSFORMED BY POLYOMA VIRUS. (E.) Vicker, M. G. (Dept. Cell Biol., U. Glasgow, Scotland) and J. G. Edwards. *J Cell Sci* 10(3):759-768, 1972.

BHK21 clone 13 hamster cells were treated *in vitro* with *Clostridium perfringens* or *Vibrio cholerae* neuraminidase. The effect of neuraminidase on the aggregation of the cells was observed, both in cases in which neuraminidase was added to a pre-aggregated culture, and in cases in which BHK21 cells were pre-incubated with neuraminidase, suspended, and aggregated in the absence of neuraminidase. Neuraminidase increased cell aggregation in both cases, but the effect was more pronounced when neuraminidase was added to pre-aggregated cells. In such cases, the mean number of cells/aggregate was doubled by neuraminidase. In contrast, the aggregation of polyoma virus-transformed BHK21 clone 13 cells was only very slightly affected by neuraminidase.

5906 STIMULATED NORMAL HUMAN LYMPHOCYTES CONTAIN A RIBONUCLEASE-SENSITIVE DNA POLYMERASE DISTINCT FROM VIRAL RNA-DIRECTED DNA POLYMERASE. (E.) Bobrow, S. N. (Natl. Cancer Inst., Bethesda, Md.), R. G. Smith, M. S. Reitz and R. C. Gallo. *Proc Nat Acad Sci USA* 69(11):3228-3232, 1972.

Lymphocytes from normal human peripheral blood were incubated with phytohemagglutinin (PHA) and then subjected to repeated centrifugation. DNA polymerase was assayed in centrifuge pellets from PHA-stimulated lymphocytes. A ribonuclease-sensitive endogenous DNA polymerase was found in the cytoplasmic particulate fraction of PHA-stimulated lymphocytes; unstimulated lymphocytes did not show this enzyme. Heteropolymeric regions of 70S RNA from avian myeloblastosis virus were not transcribed by the DNA from PHA-stimulated lymphocytes. This distinguished this DNA polymerase from the RNA-dependent DNA polymerase of human leukemic cells and oncogenic RNA viruses.

5907 PROPERTIES OF A RIBONUCLEOPROTEIN PARTICLE ISOLATED FROM NONIDET P-40-TREATED ROUS SARCOMA VIRUS. (E.) Davis, N. L. (Biophys. Lab., U. Wisconsin, Madison) and R. R. Rueckert. *J Virol* 10(5):1010-1020, 1972.

Schmidt-Ruppin Rous sarcoma virus and Bratislava Rous virus (B77) were dissociated with Nonidet P-40 and sedimented in sucrose-D₂O density gradients. A rapidly sedimenting material was detected; it contained a ribonucleoprotein (RNP) complex, as determined by sedimentation and isopycnic centrifugation. The density of the RNP-containing matter was 1.34 g/ml and its sedimentation coefficient

was 130S. Phospholipids and glucosamine were absent from the RNP-containing matter. While the complete B77 virion contained 70 4S RNA molecules/10⁷ daltons of high molecular wt (HMN) RNA, the B77 RNP contained 30 4S RNA molecules/10⁷ daltons HMN RNA. SDS electrophoresis indicated that the RNP contained only five of the 11 polypeptides found in the complete virion; the major polypeptide in the RNP material had a molecular wt of 14,000 daltons.

5908 RE-EXPOSURE OF HUMAN LYMPHOBLASTOID CELL LINES TO EPSTEIN-BARR VIRUS. (E.) Diehl, V. (Inst. Virol., U. Würzburg, West Germany), H. Wolf, H. Schulte-Holthausen and H. zur Hausen. *Int J Cancer* 10(3):641-651, 1972.

Human lymphoblastoid lines of various origins which harbor Epstein-Barr virus (EBV)-specific nucleic acid were re-exposed to EBV. Following infection, cells of the non-virus-producing lines, Raji and S 95, predominantly synthesized EBV-specific early antigens (EA), whereas only a small percentage of cells revealed viral capsid antigens (VCA). In Raji cells, the number of VCA-producing cells was paralleled by the percentage of virus-specific DNA-synthesizing cells. In S 95 cells, however, viral DNA-synthesizing cells exceeded the number of VCA-producing cells by a factor of more than ten. Induction of EA in Raji cells was dose-dependent and inversely related to cell growth. Irradiation of the virus by ultraviolet light prior to infection led to reduced infectivity. This reduction seemed to follow single-hit kinetics. Raji cells, previously re-exposed to EBV, showed reduced EA induction after re-infection with EBV, as compared to Raji control cells not previously exposed. Of ten lines which spontaneously synthesize EBV-specific antigens, seven lines proved to be refractory to re-infection, whereas three were as susceptible as the Raji and S 95 controls. From three of the refractory lines infectious virus could be recovered from the culture medium prior to infection. These results permit the following interpretations: (1) the response of human lymphoblastoid cells after re-infection with EBV results from the infecting virus and not from stimulation of endogenous genomes; (2) cells demonstrating EA synthesis ultimately die; (3) re-exposure to EBV increases the resistance to re-infection of the surviving cells; and (4) cell lines producing infectious EBV are refractory to re-infection. It is suggested that the spontaneous synthesis of infectious virus favors the selection of resistant cells.

5909 ELECTRON MICROSCOPIC STUDIES ON REPLICATING FORM OF DEFECTIVE SV 40 VIRUS DNA. (E.) Yamamoto, S. (Okayama U. Med. Sch., Japan) and T. Oda. *Arch Gesamte Virusforsch* 38(1):29-32, 1972.

Replicating circular molecules of SV 40 DNA were isolated from SV 40 infected VERO cells. Preparations from dilute and undiluted passaged SV 40 virus stocks were shown to give different frequency distri-

butions of contour length of replicating DNA molecules. The mean length of RF-DNA was $1.26 \pm 0.21 \mu$ and $1.57 \pm 0.18 \mu$ for the undiluted and dilute passaged SV 40 stocks, resp. In undiluted passaged virus stocks, small replicating molecules with a contour length less than 1.0μ were noted, which were not detected in dilute passage stocks. The presence of shortened replicating forms of DNA in the undiluted passaged virus stocks would indicate that the DNA of defective SV 40 virus can replicate.

- 5910 CAPSID STRUCTURE IN POLYOMA VIRUS. (E.)
Lecatsas, G. (Royal Postgrad Med. Sch.,
London, England) and L. Mallucci. *Arch Gesamte
Virusforsch* 37(4):340-350, 1972.

Purified preparations of polyoma virus have been studied with the electron microscope employing the technique of negative staining which allows visualization of both sides of a virus particle. Use has been made of the aberrant tubular forms of the virus in order to determine the capsomere number in the normal particle. Scale geodesic models have shown that tubules corresponding in diameter to normal particles yield an apex which is based on a 32 subunit icosahedron. Tubules based on a 42 subunit icosahedron are significantly wider than the normal particle. Similarly, tubules based on a 72 subunit icosahedron are considerably wider than the normal spherical particle, and, in addition, possess pitch characteristics which are absent in tubules closely related in diameter to normal particles. It is concluded that a 32 subunit structure for polyoma virus cannot be ruled out.

- 5911 A SPECIFIC INHIBITOR OF POLYOMA VIRUS IN
INFECTED RAT AND HAMSTER CELLS AND
IN TRANSFORMED CLONES OF HAMSTER CELLS. (E.)
Cramer, R. (Inst. Radium-Biol., Orsay, France) and
G. Meyer. *J Gen Virol* 16(3):313-326, 1972.

Extracts of polyoma virus-infected non-permissive hamster cells made 8 to 10 hr after infection stimulated polyoma virus production in permissive mouse cells, whereas extracts made after 12 hr inhibited virus production. No such inhibitor was detected within 22 hr of infection in either permissive mouse embryo cells or different established mouse cell lines or HeLa cells. An inhibitor could be extracted from hamster cell clones either transformed by polyoma virus alone or doubly transformed by polyoma and Rous sarcoma virus, but not from cells transformed by SV40 or Rous sarcoma virus alone or from cells transformed spontaneously. Polyoma virus replication was inhibited only when inhibitor was added 1 to 2 hr after infection. The inhibitor, which was sensitive to trypsin and was heat labile (60 C, 60 min), had no effect on growth or DNA synthesis of non-infected permissive mouse cells. It did, however, reduce the number of infective centers and the yield of infectious virus, infectious DNA, and of the hypercoiled form I polyoma DNA. Studies made on a permissive hybrid mouse-hamster

cell line which did not produce inhibitor indicated that non-permissiveness was not dominant but rather it seemed to depend on the presence of inhibitor which could only be expressed in non-permissive cell lines.

- 5912 AUSTRALIA ANTIGEN IN HEPATOCELLULAR CAR-
CINOMA. (E.) Simons, M. J. (W.H.O.
Immunology Res Training Ctr., U. Singapore). *Lancet*
(7786):1089-1090, 1972.

Results obtained with counterimmunoelectrophoretic methods indicate that the frequency of Australia (Au) antigen in Hong Kong and Singapore Chinese patients with hepatocellular carcinoma (HCC) is no higher than in normal individuals. However, a high proportion of HCC patients probably have Au antigen in serum concentrations below the threshold of detectability by counterimmunoelectrophoresis. A study using the more sensitive immunoadherence hemagglutination method revealed the presence of Au antigen in 55 of 156 Chinese HCC patients in Singapore.

- 5913 THE ESTABLISHMENT OF LYMPHOBLASTOID LINES
FROM ADULT AND FETAL HUMAN LYMPHOID TISSUE
AND ITS DEPENDENCE ON EBV. (E.) Nilsson, K. (Wall-
enberg Lab., U. Uppsala, Sweden), G. Klein, W. Henle
and G. Henle. *Int J Cancer* 8:433-450, 1971.

Direct and indirect immunofluorescent methods were used to detect Epstein-Barr virus (EBV)-dependent cell membrane antigens, EBV viral capsid antigens (VCA), and anti-EBV VCA antibodies in 21 continuous human lymphoblastoid cell lines (LL). The LL were established by the Spongostan grid culture method; they derived from normal and malignant lymph nodes, bone marrow and spleen cells, and peripheral leukocytes. All lines except one were EBV carriers in initial tests, but the antigens disappeared in most lines in the course of the 4-month observation period. Only eight lines maintained the initial percentage of antigen-containing cells. Reactivity of antigens in VCA and membrane immunofluorescence tests was concordant in every case. Anti-VCA antibodies were found in sera of 15 of 16 donors. In contrast to the results obtained with adult lymphoid tissue, no LL lines were established from 20 fetal cultures initiated with the Spongostan technique. However, lymphoblastoid transformation was seen in three cultures of fetal lymphoid tissue exposed to a cell-free filtrate prepared from an EBV-carrying LL lymphoblastoid cell. Filtrate from an EBV-negative line inoculated into fetal cultures did not promote the establishment of LL. These results indicate that EBV infections are not usually transmitted vertically, and that EBV infection *in vivo* or *in vitro* may be a prerequisite for the indefinite growth of lymphoblastoid cells in culture.

- 5914 AGGLUTINATION OF CELLS TRANSFORMED BY ROUS
SARCOMA VIRUS BY WHEAT GERM AGGLUTININ AND
CONCAVALIN A. (E.) Burger, M. M. (Dept. Biochem.

Sci., Princeton U., N.J.) and G. S. Martin. *Nature New Biol* 237(70):9-12, 1972.

Cultured chick embryo fibroblasts transformed by the Schmidt-Ruppin strain of Rous sarcoma virus (SR-RSV) were tested for their ability to agglutinate in the presence of wheat germ agglutination (WGA) or concanavalin A (Con A). Transformed cells exhibited only a slight increase in agglutinability compared with untransformed controls. However, pretreatment of transformed cells with purified hyaluronidase (250 IU/ml, 15 min) led to a 10- to 20-fold enhancement of agglutination with WGA and to a 6-fold increase with Con A. Pretreatment of untransformed control cells with hyaluronidase had no effect. The patterns of inhibition of agglutination by various low molecular wt carbohydrates and by ovomucoid suggested that the binding sites affected by SR-RSV were qualitatively similar to those affected by transformation with SV40 or polyoma virus. Chick cells were infected with a temperature sensitive mutant of RSV (T5) and agglutinability was tested after hyaluronidase treatment. The expression of the surface alteration occurred only at the permissive temperature (36 C). T5-infected cells grown at 36 C and shifted to the nonpermissive temperature (41 C) lost their agglutinability by 12 to 18 hr. When cells were shifted back to 36 C, agglutinability was regained. These results suggest that agglutinability of the RSV-infected cells was associated with transformation, and not with virus release, which occurred at both temperatures.

5915 DETECTION AND QUANTITATION OF SIMIAN VIRUS 40 GENETIC MATERIAL IN ABORTIVE TRANSFORMED BALB/3T3 CLONES. (E.) Smith, H. S. (Bionetics Res. Labs., Bethesda, Md.), L. D. Gelb and M. A. Martin. *Proc Nat Acad Sci USA* 69(1):152-156, 1972.

The fate of viral DNA was studied in simian virus 40 (SV40) abortively transformed BALB/3T3 clones. Such clones were contact inhibited, did not yield virus after fusion with African green monkey cells, had no SV40 tumor antigen and would not grow in serum protein-free medium. Hybridization of ³²P-labeled SV40 DNA with DNA from abortively transformed cell lines showed that viral DNA was present in increased amounts (approximately five viral genome equivalents per diploid cell) in two of the three lines studied; the third line was indistinguishable from uninfected BALB/3T3 cells. Reassociation patterns suggested that the abortive lines contained the entire SV40 genome rather than multiple partial copies. Values for three independent reclones of one of the positive lines varied from 2.7 to 10 viral DNA equivalents per diploid cell, as compared to a value of two for a standard SV40 transformant.

5916 DETECTION OF CHICKEN SARCOMA VIRUS AFTER INFECTION OF CHICKEN FIBROBLASTS WITH DNA

ISOLATED FROM MAMMALIAN CELLS TRANSFORMED WITH ROUS VIRUS. (E.) Svoboda, J. (Czechoslovak Acad. Sci., Prague), I. Hloaznek and O. Mach. *Folia Biol (Praha)* 18(2):149-153, 1972.

DNA was extracted by the phenol method from XC cells, which carried the Prague Rous sarcoma virus (PR-RSV) genome, or from hamster RSCH cells, which carried the Schmidt-Ruppin RSV (SR-RSV) genome. These DNAs were used to treat BLEF chicken embryo fibroblasts. Three viruses capable of transforming BLEF were released by DNA-treated BLEF cells. One virus recovered from XC cells induced sarcoma growth when injected into chickens. All viruses produced typical pocks on the chicken chorioallantoic membrane.

5917 DETERMINATION OF PHOSPHOLIPID COMPOSITION OF RNA TUMOR VIRUSES BY ³²P LABELING OF INFECTED CELL CULTURES. (E.) Quigley, J. P. (Rockefeller U., New York, N.Y.), D. B. Rifkin and M. H. Einhorn. *Anal Biochem* 47(2):614-619, 1972.

The phospholipid composition of the viral envelope of a high-titer variant of the Schmidt-Ruppin strain of Rous sarcoma virus (RSV) was studied by thin-layer chromatography. RSV-infected chick embryo fibroblast (CEF) cultures were incubated with ³²P and at various times the cellular and viral phospholipids were extracted and the percentage of the total ³²P radioactivity of each phospholipid species was determined. After four days of labeling, the specific activity of phosphorus was the same in all species of cellular and viral phospholipids. The percentage distribution of radioactivity of the different classes of phospholipids differed between the CEF membrane and the virus envelope extracts. The major component of the CEF membrane was phosphatidyl choline (PC) which comprised about 50% of the total membrane phospholipids. Phosphatidyl ethanolamine (PE), phosphatidyl inositol (PI) + phosphatidyl serine (PS) and sphingomyelin (sph) comprised approximately 25%, 20% and 10%, resp. In contrast, the RSV envelope contained relatively more sph (30%) and relatively less PC (25%) and PI + PS (10%). Determinations of percentage composition based on ³²P incorporation agreed well with the percentage composition determined by chemical methods.

5918 IN VITRO CELL TRANSFORMATION BY HERPES-VIRUSES. (E.) Rapp, F. (M. S. Hershey Med. Ctr., Pennsylvania State U.) and R. Duff. *Fed Proc* 31(6):1660-1668, 1972.

Herpes simplex virus type 2 (HSV-2) previously exposed to ultraviolet radiation induced foci with altered morphology and loss of contact inhibition in cultures of hamster embryo fibroblasts (HEF). A total of four HSV-2 strains of the 12 tested transformed the HEF cells. Cell lines established from several clonal isolates of transformed foci induced fibrosarcomas when injected into newborn Syrian hamsters. These tumors were invasive and

induced metastatic tumors often seen in the lungs of the injected animals. The HSV-2 transformed hamster cells contained herpesvirus specific antigens in the cytoplasm of 1-5% of the cells. These virus antigens were detected by indirect immunofluorescence techniques. Tumor-bearing hamsters also developed antibodies in the serum capable of neutralizing HSV-2. The neutralizing titer of each serum was directly proportional to the length of time the host animal carried the tumor. Tests for the presence of C-type virus particles or C-type virus antigens were uniformly negative. However, electron-microscopy studies have detected herpeslike particles in a few of the transformed cells. The results are most compatible with the hypothesis that the inactivated herpesvirus transformed the cells and that expression of the virus genome is repressed in most cells in the culture. In this respect, the observations closely parallel those made with other suspected and known oncogenic herpesviruses.

- 5919 RESCUE OF THE MURINE SARCOMA VIRUS GENOME FROM NON-PRODUCER CELLS BY THE RD-114 TYPE C VIRUS. (E.) Gilden, R. V. (Flow Lab., Inc., Rockville, Md.), Y. K. Lee and C. Long. *Int J Cancer* 10(3):458-462, 1972.

A pseudotype focus-forming virus was rescued from non-producer murine sarcoma virus-transformed hamster HT-1 cells following their fusion with human RD cells freshly infected with RD-114 virus, a suspected human C-type virus. The rescued virus, MSV(RD-114), showed transforming activity against cultured skin, muscle, or whole human embryo fibroblasts and against WI-38 cells, but not against mouse, rat, or hamster embryo cells. Initial results suggested a one-hit titration pattern. The pseudotype MSV(RD-114) virus population contained both the envelope and gs antigens characteristic of RD-114, the rescuing helper virus. Anti-RD-114 reverse transcriptase antibody completely inhibited MSV(RD-114) reverse transcriptase. Human fibroblast cultures infected with RD-114 were completely resistant to focus formation by MSV(RD-114), whereas MSV(RD-114) could transform human fibroblast cultures replicating feline leukemia virus.

- 5920 CELL-MEDIATED REACTION AGAINST TUMORS INDUCED BY ONCORNAVIRUSES. I. KINETICS AND SPECIFICITY OF THE IMMUNE RESPONSE IN TUMORS AND TRANSPLANTED LYMPHOMAS (E.) Leclerc, J.C. (St. Louis Hosp., Paris, France), E. Gomard and J. P. Levy. *Int J Cancer* 10(3):589-601, 1972.

Cell-mediated anti-tumor immunity was studied by the ^{51}Cr release assay in C57Bl(B6) and BALB/c mice bearing autochthonous murine sarcoma virus (MSV)-induced sarcomas or bearing syngeneic transplants of lymphomas with various antigenic specificities. By 12 to 15 days after MSV injection or s.c. Moloney or Graffi lymphoma transplantation, spleen and lymph node cells from animals with both progressively growing ("progressors") and with regressing ("regressors")

tumors were clearly cytotoxic for isologous specific ^{51}Cr -labeled target cells. Thereafter, cytotoxic lymphoid cells disappeared rapidly in progressors, but more slowly in regressors. The level of cytolytic activity of lymphoid cells from the spleen of regressors did not, however, parallel the immune protection. No enhancement of existing cell-mediated anti-tumor activity was observed when mice which had rejected their initial tumor were re-inoculated with MSV or with lymphoma cells. No specific blocking activity was seen in sera from progressor or regressor mice. Since specific blocking by antisera could not be used to study the specificity of the immune cytotoxicity by lymphoid cells, it could not be determined whether the antigens detected by the ^{51}Cr release assay were identical to those identified by complement-dependent cytotoxicity or by immunofluorescence tests on living cells using sera from the same animals. The antigenic specificity of the immune reactions detected by the ^{51}Cr release assay was not identical to those revealed by the serological methods.

- 5921 POLY(rA) TRACTS OF TUMOR VIRUS 70S RNA ARE NOT TRANSCRIBED IN ENDOGENOUS OR RECONSTITUTED REACTIONS OF VIRAL REVERSE TRANSCRIPTASE. (E.) Reitz, M. (Bionetics Res. Lab., Bethesda, Md.), D. Gillespie, W. C. Saxinger, M. Robert and R. C. Gallo. *Biochem Biophys Res Commun* 49(5):1216-1224, 1972.

DNA transcripts prepared from reconstituted (purified DNA polymerase and exogenous 70S RNA) and endogenous reverse transcriptase reactions of avian myeloblastosis virus (AMV) were analyzed by two different molecular hybridization techniques. In addition, DNA from the reconstituted reaction was prepared both with and without oligo(dT) added as a synthetic primer. The DNA transcripts were then analyzed for poly(dT) content and for nucleotide sequences complementary to homologous and heterologous 70S RNA. The results showed that the poly(rA) region of AMV 70S RNA was not transcribed unless oligo(dT) was added as primer and that at least some of the poly(dT) synthesized in the oligo(dT)-stimulated reaction was covalently bound to heteropolymeric transcripts. These results indicated that 3'-OH groups of the resident primers did not reside within the poly(rA) regions and that poly(rA) was probably added post-transcriptionally to the viral RNA.

- 5922 RIBONUCLEASE H: A UBIQUITOUS ACTIVITY IN VIRIONS OF RIBONUCLEIC ACID TUMOR VIRUSES. (E.) Grandgenett, D. P. (St. Louis U. Sch. Med., Missouri), G. F. Gerard and M. Green. *J Virol* 10(6):1136-1142, 1972.

Ten ribonucleic acid (RNA) tumor viruses grown in five different host cell species and three non-oncogenic viruses from three different virus groups have been examined for ribonuclease H content. Three different substrates were used to assay ribonuclease H: calf thymus [^3H]RNA-deoxyribonucleic

id (DNA) hybrid prepared with denatured calf thymus DNA and *Escherichia coli* DNA-directed RNA polymerase, ^3H -polyadenylic acid [^3H -poly(a)] complexed to polydeoxythymidylic acid [poly(dT)], and ^3H -polyuridylic acid [^3H -poly(U)] complexed to polydeoxyadenylic acid [poly(dA)]. All ten RNA tumor viruses contained ribonuclease H activity which degraded the RNA of both the calf thymus hybrid and poly(a)-poly(dT), whereas only the ribonuclease H in the Moloney strain of murine sarcoma-leukemia virus and in RD-feline leukemia virus hydrolyzed the RNA strand of poly(U)-poly(dA). No appreciable ribonuclease H activity was detected in influenza, Sendai, or vesicular stomatitis virus. The ribonuclease H and RNA-directed DNA polymerase activities in Moloney murine sarcoma-leukemia virus were inseparable by phosphocellulose chromatography or glycerol gradient centrifugation, but appeared to be partially separated by diethylaminoethyl-cellulose chromatography.

923 CELL-MEDIATED DESTRUCTION OF ROUS SARCOMAS IN JAPANESE QUAILS. (E.) Hayami, M. (Washington Med. Sch., Seattle, Wash.), I. Hellström, K. E. Hellström and K. Yamanouchi. *Int J Cancer* 10(3):507-517, 1972.

A microcytotoxicity test was used to study the destruction of cultivated Rous sarcoma cells by thymus, spleen and bursa cells from Japanese quails whose Rous sarcomas had regressed ("regressors") and from quails with progressively growing tumors ("progressors"). Regressor spleen cells were slightly more cytotoxic than regressor thymus cells in showing a cytotoxic effect against cultured Rous sarcoma cells. Bursa cells from regressors showed no cytotoxic activity. Autochthonous and allogeneic lymphoid cells from regressors were equally cytotoxic. No cytotoxic effect was observed, however with lymphoid cells from progressors. Surgical bursectomy on the day of hatching, which depressed the production of antibodies against sheep red blood cells, slightly enhanced the ability of spleen cells from regressors to destroy cultivated Rous sarcoma cells. Spleen cells from thymectomized progressors which showed delayed skin graft rejection were not significantly cytotoxic. Progressor spleen cells could abolish the cytotoxic effect of regressor spleen cells from nonbursectomized quails but not those from bursectomized birds.

924 BIOCHEMICAL TRANSFORMATION OF L-CELLS WITH ULTRAVIOLET-IRRADIATED HERPES SIMPLEX VIRUS. (E.) Munyon, W. (Roswell Park Mem. Inst., Buffalo, N.Y.), E. Kraiselbund, D. Davis, R. Zeigel, A. Buchsbaum and E. Paoletti. *Fed Proc* 31(6):1669-1673, 1972.

Ltk minus cells can be stably converted to Ltk plus cells by infecting them with ultraviolet irradiated herpes simplex virus. This conversion consists of 1) acquiring the ability to use exogenous thymidine for the synthesis of cellular DNA and 2) an increase in the amount of thymidine kinase activity by a fac-

tor of 15-21 times relative to the low background level of thymidine kinase present in Ltk minus cells. Cell lines derived from clones of cells that have acquired these new characteristics have been called herpes simplex virus-transformed cells. The thymidine kinase activity present in the herpes simplex virus-transformed cells is different from the thymidine kinase present in normal L-cells with respect to migration during polyacrylamide gel electrophoresis and with respect to the kinetics of thermal inactivation. By these criteria, the thymidine kinase induced during the course of a lytic infection by herpes simplex virus is similar to the thymidine kinase found in the herpes simplex virus-transformed cells. These data support the notion that the herpes simplex virus-transformed cells have acquired the herpes simplex virus gene coding for thymidine kinase production.

5925 HERPESVIRUSES SAIMIRI AND ATELES--THEIR ROLE IN MALIGNANT LYMPHOMAS OF MONKEYS. (E.) Melendez, L. V. (Harvard Med. Sch., New England Regional Primate Res. Ctr., Southboro, Mass.), R. D. Hunt, M. D. Daniel, C. E. O. Fraser, H. H. Barahona, N. W. King and F. G. Garcia. *Fed Proc* 31(6):1643-1650, 1972.

This report indicates that *Herpesvirus saimiri* and *Herpesvirus ateles*, the first two oncogenic herpesvirus from primates, are unrelated viruses. They differ from each other in the following properties: cytopathogenicity (*H. ateles* has a wider *in vitro* host range than *H. saimiri*; plaquing capacity (*H. ateles* forms plaques in hamster cell cultures and *H. saimiri* does not); antibody development (*H. saimiri* produces good level of antibodies in goats and none in rabbits while *H. ateles* behaves inversely in the same species); antigenic relationship (no cross-neutralizing nor cross-fluorescing antibodies were detected); pathogenicity in rabbits (*H. saimiri* induces malignant lymphoma but this was not observed with *H. ateles*); oncogenic spectrum; in *in vivo* conditions *H. ateles* is more oncogenic than *H. saimiri* in cottontop marmosets (*Saguinus oedipus*). But *H. saimiri* so far has the widest oncogenic spectrum of known DNA oncogenic viruses.

5926 PARTICLES CONTAINING RNA-INSTRUCTED DNA POLYMERASE AND VIRUS-RELATED RNA IN HUMAN BREAST CANCERS. (E.) Axel, R. (Coll. Phys. Surg., Columbia U., New York, N.Y.), S. C. Gulati and S. Spiegelman. *Proc Nat Acad Sci USA* 69(11):3133-3137, 1972.

Tissues from 38 human breast adenocarcinomas were subjected to repeated centrifugation and added to a standard endogenous RNA-directed DNA polymerase reaction mixture. The mixtures were assayed for ability to synthesize a 70S RNA-DNA complex. Seventy-nine percent of adenocarcinoma tissues produced the 70S component, encapsulated with RNA-instructed DNA polymerase in a particle with the density characteristics of RNA tumor viruses. The complex was not

detected in normal breast tissue or in fibro-adenoma tissue. The DNA synthesized by the human RNA enzyme complex hybridized specifically with the RNA of mouse mammary tumor virus.

5927 ON MECHANISMS OF FORMATION AND PENETRATION INTO THE CELL OF MURINE LEUKEMIA VIRUSES.

- 5957 INHIBITION BY LYMPHOCYTE NUCLEI OF DNA AND RNA SYNTHESIS IN STIMULATED LYMPHOCYTES AND LEUKAEMIC CELLS. (E.) Pegrum, G. D. (Charing Cross Hosp. Med Sch. London, England) and E. Thompson. *Brit J Exp Path* 52(2):560-564, 1971.

Lymphocyte preparations were obtained and cultured from 33 healthy donors, 15 patients with acute leukemia, 12 patients with chronic lymphatic leukemia and ten patients with chronic myeloid leukemia. Normal lymphocytes were stimulated with phytohemagglutinin (PHA) 24 hr before the start of the experiment. On the day of the experiment, preparations of lymphocytic nuclei free of cytoplasmic contamination and taken from fresh blood samples from normal donors were placed in the PHA-stimulated and the leukemic cultures. After three or six days of growth, samples of each culture were labeled with ^3H -thymidine or ^3H -uridine so that the rate of DNA or RNA synthesis could be determined. Cultures of leukemic cells, lymphocytes and nuclei incubated alone were used as controls. DNA and RNA synthesis was inhibited in seven of 16 treated PHA-stimulated cultures on day three and in 15 of 16 cultures after six days. Where there was depression of DNA synthesis, the number of transformed cells was also clearly reduced. Normal lymphocyte nuclei free of cytoplasmic contamination also inhibited DNA and RNA synthesis in acute leukemic cells, the chronic lymphatic leukemic cells and the chronic myeloid leukemic cells. No inhibition of ^3H -thymidine incorporation was seen in five control cultures using PHA stimulated nuclei alone.

- 5958 THE LYMPHOCYTES OF CHRONIC LYMPHOCYTIC LEUKEMIA: THEIR PROLIFERATION AND CELL CYCLE KINETICS. (E.) Johnson, L. I. (Mt. Sinai Sch. Med., New York, N.Y.), J. LoBue and A. D. Rubin. *Cell Tissue Kinet* 5:27-34, 1972.

Lymphocytes cultured in diffusion chambers and implanted, i.p., in rats were double labeled using tritiated thymidine (^3H -TdR) and ^{14}C thymidine, and double-emulsion autographs were tabulated according to whether overlying grains were present only in the ^3H -labeled layer or in both ^3H - and ^{14}C -labeled layers. When treated with phytohemagglutinin (PHA) CLL cultures showed a maximum percentage of blast cells occurring at 5-7 days, compared to the usual 2-3 days of normal lymphocyte transformation. Kinetics of proliferation in the late-developing CLL blasts was compared with results obtained with blasts developing in normal lymphocyte cultures. Following ^3H -TdR pulse labeling of PHA-treated CLL cultures, blasts appeared to enter mitosis at a slower rate, possibly due to a T_{G2} (post-DNA synthesis, pre-mitotic time) more variable than in normal blasts. Estimated $T_{G2}+T_m$ (mitotic time) for CLL blasts was 3.5 hr compared to 2.5 hr for normal blasts. Labeling index (LI) was used to estimate T_c (cell cycle time). A lower mitotic index in CLL blasts was observed. DNA synthesis was calculated to be 8-10 hr, consistent with normal and CLL blast cells. In both the double label procedure and the labeled mitosis technique cell cycle estimates for CLL lymphocytes were within

the normal range of values found for normal blast cells.

- 5959 OBSERVATIONS ON THE ULTRASTRUCTURE OF TWO HAMSTER LYMPHOMAS WITH PARTICULAR REFERENCE TO INFILTRATING MACROPHAGES. (E.) Birbeck, M. S. C. (Chester Beatty Res. Inst., London, England) and R. L. Carter. *Int J Cancer* 9(2):249-257, 1972.

Two transplantable hamster lymphomas, one of which (ML) metastasizes, while the other (NML) only grows at the site of implantation, were examined in the electron microscope. The tumor cells of the two lymphomas were found to be identical except for a slightly greater amount of endoplasmic reticulum on ML; both contain the typical ultrastructural features of experimental tumor cells, including viral particles. The difference between the two tumors was found to be in the invading host macrophages. The macrophages in NML are large cells containing phagosomes filled with tumor cells in varying stages of digestion. ML also contains macrophages but these are small cells without phagosomes, which accounts for their not being found in earlier light microscope studies. That these latter cells are macrophages is evident from their membrane processes and the presence of primary lysosomes. The failure to find any basic ultrastructural differences between ML and NML cells strengthens the argument that the fundamental differences between these two tumors lie primarily in the host response that they evoke.

- 5960 CHANGES IN TOTAL GAMMA GLOBULIN CONTENT AND IN IMMUNOGLOBULINS G, A AND M IN THE SERUM OF CHILDREN WITH LEUKEMIA: COMMUNICATION II. QUANTITATIVE CHANGES OF IMMUNOGLOBULINS G, A AND M IN THE SERUM OF CHILDREN WITH LEUKEMIA. (Ger.) Blau, H.-J. (U. Pediat. Clin., Rostock, East Germany). *Folia Haematol* 97(3):146-156, 1972.

The immunoglobulin picture in relation to the different stages of leukemia in children is described. The results were obtained in 222 serum tests in 32 children with leukemia (25 with paraneoplastic leucosis, three with acute and four with chronic myeloid leukemia), and in 21 healthy children, by means of simple radial immunodiffusion and the Mancini test. Sera of children in remission had a lower IgG value than sera of those with a relapsed form, although no statistical significance could be demonstrated. Mean IgM values revealed a statistical decrease in the remission stage compared with the onset of paraneoplastic leucosis. The IgA values in the various stages of the disease were quite constant. During stable remission, despite cytostatic treatment at various intervals, children with paraneoplastic leucosis have serum gamma globulins within the normal range; although the IgG is decreased, the IgM and IgA values bring the total gamma globulins up to the normal value. With a relapse, there is a decrease in IgG which is more marked than that of IgM. Thus, in paraneoplastic leucosis, the IgG changes are foremost, IgM changes are slighter and IgA changes are rare. In children with acute or the juvenile form of a

chronic myeloid leukemia, the various fractions of the gamma globulins are analogous to the values in paraneoplastic leucosis or higher. In chronic myeloid leukemia, similar to the adult type, the IgG and IgM values, particularly in the progressive phases, are high; in the less progressive phases these values are within normal limits.

5961 BLASTIC STIMULATION BY PHYTOHEMAGGLUTININ (PHA) AND NATURAL ROSETTE TEST IN CANCEROLOGY. (Fr.) Serrou, B. (Dept. Immunol. C.R.L.C., Montpellier, France), C. Girard and C. Romieu. *Travaux Soc Pharmacie Montpellier* 32(1):27-34, 1972.

Cellular and humoral immunity factors were investigated in 100 patients with various neoplasias (Hodgkin's, otorhinolaryngological areas, reticulosarcoma, solid tumors). Serum complement, C'3 reaction, and the immunoglobulins IgA, IgG, and IgM were determined for humoral immunity. For the cellular immunity, a series of skin tests were conducted. These were *in vitro* lymphoblastic transformation in the presence of phytohemagglutinin (PHA) and the formation of natural rosettes. The normal hemolytic value, used for the determination of the complement, was determined as 50% (H₅₀); this result was increased in the patient population up to 80 or 100 hemolytic units. No marked variations in immunoglobulins were seen except in patients treated by immunotherapy. The test for lymphoblastic stimulation by PHA indicated a lower degree of transformation in the patients (compared with normals). In normal subjects, PHA stimulation caused an increase in the degree of transformation from 0-7% to 77%; in Hodgkin's disease, the stimulation showed a mean of 9%. The rosette test used consists of an agglutination of sheep red blood cells on the lymphocyte membrane at the sites of immunoglobulins. Isolation of lymphocytes by gradient concentration is effected with the aid of the Ficoll-Triosil method. The number of natural rosettes varied from 50 to 80/1000 in normal subjects, was below 10/1000 in patients with Hodgkin's disease and could rise to 40/1000 upon immunotherapy. Patients with tumors involving otorhinolaryngological organs had natural rosette numbers comparable or higher than normal subjects.

5962 DELAYED HYPERSENSITIVITY REACTIONS IN PATIENTS WITH MALIGNANT BRAIN TUMORS TO HUMAN TUMOR CELL LINES GROWN *IN VITRO*. (Fr.) Febvre, H. (Cellular Biol. Unit, I.N.S.E.R.M., Paris, France), J. Maunoury, J. P. Constans and P. Trouillas. *Int J Cancer* 10:221-232, 1972.

The detection of immunity in patients with malignant brain tumors by means of human neoplastic cells grown *in vitro* is described. Most of the antigenic material in the study was taken from cells that had been isolated in the laboratory from surgical specimens; the origin of the cells and the date when culture was begun are tabulated. Controls were obtained by direct lyophilization of normal and pathological tissues. Hypersensitivity reactions were tested before two to three wk after surgical intervention,

with some patients followed for longer periods. These tests were conducted under blind control. Patients operated on for cerebral tumors and hyperimmunized with their own tumors had strongly positive intradermal reactions. Intradermal inoculation of 2 mg protein, in distilled water, from the antigenic material also produced strong reactions in these patients. Reactions elicited from patients with benign or malignant tumors before surgery were all negative. Patients with autologous or recidivous grafts showed positive reactions to the antigens; this was also the case with patients who had extra-cerebral, terminal cerebral, or infiltrated and necrosed tumors. In patients with malignant tumors in general, a non-specific antigenic histologic type stimulation exists which is associated with the existence of tumor cells in the organism. This antigenic stimulation is revealed by so-called "strong" antigens generated by *in vitro*-cultivated malignant brain tumor cells.

5963 DEMONSTRATION OF GRAFFI VIRUS-INDUCED AND SPECIES-SPECIFIC SURFACE ANTIGENS IN RAT GRAFFI LEUKEMIA CELLS, USING IMMUNOELECTROMICROSCOPIC TECHNIQUES. (Ger.) Micheel, B. (Cancer Res. Inst. German Acad. Sci., Berlin, Germany), D. Bierwolf, A. Randt, H. Franz, J. Mohr and G. Pasternak. *Acta Biol Med Germ* 27(3):639-649, 1971.

The use of ferrocene as an antibody marker for differentiating antigen specificity of leukemia cells by electron microscopy is described. Since ferrocene-marked antibodies are observed as amorphous, in distinction to the ferritin-marker granular forms, immunoelectron microscopic techniques were employed to establish whether normal cellular antigens are formed in the extracellular envelopes of the virus particles and if the virus-free membrane areas, in which virus-induced antigens are located, contain normal cellular antigens. The results revealed that antisera against normal (rat-specific) membrane antigens do not react with the extracellular Graffi-virus particle envelopes, and that on the surfaces of leukemia cells, there are discrete areas which do not contain antigens. These areas possibly contain only Graffi-virus-induced antigens. In this test, ferritin is used as the marker for the antigens (species-specific) and ferrocene marks the Graffi-virus-induced antigens. When leukemia cells are incubated with normal mouse serum and antimouse globulin marked with ferritin and ferrocene, there is no marking of viral or cellular structures. The results support the presumption of a correlation between the presence of viral antigens in the cell membrane and the formation of virus particles.

5964 SURFACE ANTIGEN AND POLYPSEUDOPODIA IN ABORTIVE TRANSFORMATION OF BHK 21 CELLS BY POLYOMA VIRUS. (E.) Stoker, M. G. P. (Imperial Cancer Res. Fund Lab., London, England), M. Thornton, P. Riddle, F. Birg and G. Meyer. *Int J Cancer* 10(3):613-618, 1972.

BHK 21 cells were exposed to high multiplicities of

polyoma virus. A change in surface antigen was detected by immunofluorescence, beginning at 18 hr and affecting up to 88% of cells 24 hr after infection. Time-lapse cinematography showed that there was a concurrent change in movement and shape (polypseudopodia) of the cells in the confluent layer, involving about the same proportion of cells. Both these changes appeared before the virus-induced stimulation of the thymidine incorporation and mitosis, and before the increase in lectin agglutinability. The S antigen disappeared more rapidly than the polyspseudopodia in these abortively transformed cells, but both persisted in stably transformed cells. The antigenic change and polyspseudopodia were not the result of the virus-induced stimulation of cell DNA synthesis and mitosis.

- 5965 ALTERATION OF ONCOGENIC PROPERTIES OF RAT RETICULOSARCOMAS UNDER THE EFFECT OF COMPLETE FREUND'S ADJUVANT. (Rus.) Gordienko, S. P. (P. A. Gertsen Moscow Res. Inst. Oncol., USSR) and A. I. Ageenko. *Biul Eksp Biol Med* 72(10):88-92, 1971.

The effects of complete Freund's adjuvant (CFA), prepared from tuberculous mycobacteria, on the growth of tumor transplants and oncogenicity of cell-free extracts of rat reticulosarcoma 321-KPC were studied. A cellular suspension of reticulosarcoma 321-KPC (3.5×10^5) was inoculated into the dorsal skin of 30 Wistar rats 10 days after the i.m. injection of 0.04 ml CFA into the hind paw. Tumors occurred in all rats, 26 of which had intraperitoneal tumors. The average tumor latent period was 90 days. In contrast, local tumors but no intraperitoneal tumors were observed in four of 30 control rats not pretreated with CFA. The average latent period was 17 days. Of 20 rats given CFA prior to inoculation of 3.5×10^6 reticulosarcoma cells into spinal skin, 13 had intraperitoneal reticulosarcoma, the latent period being 160 days. The cell-free extract of rat reticulosarcoma 321-KPC alone did not induce tumors in any newborn Wistar rats, but tumors occurred in 44/95 (45%) of newborn rats simultaneously inoculated with CFA and the extracellular extract. The latent period was 136 days.

- 5966 ANTIGEN SOLUBILIZED FROM HUMAN LEUKEMIA: LYMPHOCYTE STIMULATION. (E.) Gutterman, J. U. (M. D. Anderson Hosp. Tumor Inst., Houston, Texas), G. Mavligit, K. B. McCredie, G. P. Bodey, Sr., E. J. Freireich and E. M. Herish. *Science* 177(4054):1114-1115, 1972.

Tumor antigen was extracted from blast cells of seven leukemia patients by treatment with hypertonic (3 molar) KCl. Normal allogeneic lymphocytes and lymphocytes from blast cell donors (autologous lymphocytes) were exposed to soluble tumor antigen or to stimulator leukemia cells and the blastogenic response of lymphocytes was noted. Six of the seven autologous lymphocyte pools showed a significant

blastogenic response to soluble antigen and five of these seven pools responded to stimulator leukemic lymphocytes. Normal allogeneic lymphocytes showed a blastogenic response to only one of the seven soluble tumor antigen preparations, but responded to six of seven stimulator leukemic cell preparations. The use of soluble antigen should facilitate the study of specific tumor immunity in human leukemia.

- 5967 DETECTION OF TUMOUR-ASSOCIATED TRANSPLANTATION ANTIGEN OF BO-IV CARCINOMA ON SOMATIC CELLS OF TUMOUR-FREE SYNGENEIC MICE. I. DEMONSTRATION OF THIS ANTIGEN ON SPLEEN CELLS. (E.) Rejthar, A. (Fac. Med., Purkyne U., Brno, Czechoslovakia). *Folia Biol* 18(2):132-138, 1972.

The genetic homogeneity of CBA/j mice was verified by isotransplantation of skin grafts. Fifteen CBA/j mice were then immunized against transplantable BO-IV round-cell carcinoma by s.c. injection of irradiated tumor cells. This regimen increased resistance to BO-IV challenge; immunized mice survived 4.9 days longer than unimmunized mice. Mice challenged with BO-IV and concomitantly given spleen cells from immunized mice survived five days longer than mice given the challenge and spleen cells from untreated donors. Mice immunized with syngeneic spleen cells a week before BO-IV challenge showed a highly significant increase in resistance to tumor growth; their mean survival time was 6.5 days longer than that of controls. Serum from immunized mice, injected into mice challenged with constant doses of BO-IV cells, produced a passive immunological enhancement of tumor growth. It was concluded that BO-IV cells carried a true tumor-associated transplantation antigen, and that spleen cells of tumor-free mice carried an identical antigenic structure.

- 5968 THE EFFECT OF SOME ALKYLATING AGENTS AND THE WHOLE-BODY IONIZING IRRADIATION ON THE FORMATION AND REALIZATION OF THE IMMUNOLOGICAL MEMORY. (Rus.) Kazaryan, K. A. (N. F. Gamaleya Inst. Epidemiol. Microbiol., Acad. Med. Sci. USSR, Moscow), L. N. Fontalin, L. A. Pevnitskii and V. V. Solov'ev. *Biul Eksp Biol Med* 72(11):58-61, 1971.

The effects of alkylating agents on the formation of the immunologic memory and secondary immune response were studied in mice. Adult hybrid white mice were immunized with a small dose of sheep erythrocytes (1×10^6) injected i.v. twice at intervals of 27-44 days. The alkylating agents--sarcosyl, 8 mg/kg/day for four days; thio-TEPA, 8 mg/kg/day for four days, degranol, 25 mg/kg/day for two days and cyclophosphamide 200 mg/kg (single dose)--were administered i.p. to the mice at the time of first or second immunizations, or in the interval between them. The animals were irradiated with 500 r Co once before or after immunization. The number of antibody-forming cells in the spleen were determined by Jerne's method four days after the second immunization. All the agents sharply suppressed

realization of the immunologic memory, measured by the IgM antibody production in the secondary response: Sarcolysin, degranol, cyclophosphamide, and radiation suppressed the secondary response, and thio-TEPA significantly weakened it. Another series of experiments revealed that the formation of the immunologic memory was radioresistant but sensitive to cyclophosphamide, whereas the cell carriers of the already-formed memory were radiosensitive but stable to the agents.

- 5969 EPSTEIN-BARR VIRUS (HERPES-TYPE VIRUS) ANTIBODIES IN CONNECTIVE TISSUE DISEASES. (E.) Stevens, D. A. (Natl. Cancer Inst., Bethesda, Md.), M. B. Stevens, G. R. Newell, P. H. Levine and D. F. Waggoner. *Arch Intern Med* 130(1):23-28, 1972.

Serum specimens from female patients with connective tissue diseases were tested for anti-Epstein-Barr virus (EBV) antibody by immunofluorescence and immunodiffusion. The patients included 34 with systemic lupus erythematosus (SLE) with or without nephritis, 11 with rheumatoid arthritis, six with polymyositis and 12 with systemic sclerosis. No significant differences were seen in percentages of sera with positive immunofluorescence patterns between patients and normal controls. A particular pattern of nuclear fluorescence was noted in 75-85% of cells; areas of fluorescence were arranged in crossing strands to form a web. In immunodiffusion tests against EBV antigens, sera from SLE patients with or without nephritis had a greater mean number of reaction bands than controls, though not more than other patient groups.

- 5970 REVERSE TRANSCRIPTASES OF PRIMATE VIRUSES AS IMMUNOLOGICAL MARKERS. (E.) Scolnick, E. M. (Natl. Cancer Inst., Bethesda, Md.), W. P. Parks and G. J. Todaro. *Science* 177(4054):1119-1121, 1972.

Studies were undertaken to determine the immunological relations between the DNA polymerases ("reverse transcriptases") of type C viruses isolated from a woolly monkey fibrosarcoma and from a gibbon ape lymphosarcoma, the Mason-Pfizer monkey virus (MP-MV) isolated from a mammary adenocarcinoma of a rhesus monkey, and foamy viruses isolated from several primate species. Antiserum prepared against the woolly monkey tumor virus RNA polymerase could also inhibit the gibbon-type polymerase but not the polymerases from the MP-MV and the foamy viruses. Antiserum prepared against the MP-MV polymerase did not inhibit the activity of any of the other primate viral polymerases. Antiserum prepared against a type C virus (RD-114) isolated from a human rhabdomyosarcoma grown in fetal cat brain did not affect woolly monkey, gibbon ape, avian, or feline type C virus polymerase. Antisera against woolly monkey and gibbon ape tumor virus polymerases did not comparably inhibit RD-114 polymerase activity. These results indicated that the polymerases from the woolly monkey and gibbon ape tumors are immunologically related to

each other and are distinct from the C-type viruses isolated from other mammals.

- 5971 A HETERO-ORGANIC ANTIGEN OF A RAT ASCITES HEPATOMA. (E.) Satoh, S. (Sch. Med., Hokkaido U., Sapporo, Japan). *Gann* 63:579-590, 1972.

Rat ascites hepatoma (AH-272) ascites were centrifuged and the antigen-containing soluble extract was reacted in agar gel precipitation tests with anti-AH-272 rabbit antisera. Absorbed antisera which failed to react with extracts from normal rat tissue formed a clear precipitation line with the AH-272 antigen-containing solution. In immunoelectrophoresis, AH-272 antigen solution formed a precipitation arc against the absorbed antiserum at the position of the serum α_2 -globulin. AH-272 antigen was quantitated in normal rat tissues; it was present in the largest amounts in placenta. Immunofluorescence and cellular fractionation of AH-272 cells indicated that the antigen was present in the soluble structure of the cytoplasm. Purified, the AH-272 antigen was characterized physicochemically as a protein of molecular wt 40,000-50,000.

- 5972 RADIOIMMUNOASSAY FOR α_1 -FETOPROTEIN IN THE SERUM OF RATS. (E.) Oaks, D. D. (Montreal Gen. Hosp., Quebec, Canada), J. Shuster and P. Gold. *Cancer Res* 32(12):2753-2760, 1972.

A radioimmunoassay for the detection of α_1 -fetoprotein (AFP) in the sera of rats is described. The procedure is based on the preparation of purified and radiolabeled AFP, monospecific anti-AFP antiserum, and a modification of the coprecipitation-inhibition technique in 50% saturated ammonium sulfate. A detailed description is given of the combination of immunochemical and physicochemical methods used in the purification of the rat AFP. The purified rat AFP is virtually identical to the native, circulating AFP by immunological criteria and contains, at most, trace contamination with other materials. The radioimmunoassay has a sensitivity that allows 25 ng AFP per ml of serum to be detected with reproducibility. The assay requires 20 μ l of serum for analysis and can be completed within a few hours.

- 5973 INCREASED ANTIBODY TO HERPES SIMPLEX VIRUS IN PATIENTS WITH NASOPHARYNGEAL CANCER. (E.) Palmer, E. L. (Ctr. Dis. Control, Atlanta, Ga.), P. M. Feorino and M. L. Martin. *J Infect Dis* 126(2):186-188, 1972.

Sera from patients with nasopharyngeal cancer, Burkitt's lymphoma, and primary infection with herpes simplex virus, and sera from controls were tested for antibodies to herpes simplex virus by the complement-fixation test and for antibodies to Epstein-Barr virus by fluorescent-antibody test. Sera from patients with nasopharyngeal cancer contained elevated levels of antibody to both herpes simplex and Epstein-Barr viruses, whereas sera from

patients with Burkitt's lymphoma contained elevated levels of antibody to Epstein-Barr virus only. Titers of antibodies to subunits of herpes simplex virus in the sera of patients with nasopharyngeal cancer were higher than those in control sera. The levels of antibody were markedly similar to those in convalescent-phase sera of individuals with recent primary infection with herpes simplex virus. The antibody profiles of some patients with nasopharyngeal cancer were consistent with reactivated, latent infection with herpes simplex virus.

- 5974 MACROPHAGE MIGRATION INHIBITION WITH MOUSE TUMOR ANTIGENS: PROPERTIES OF SERUM AND PERITONEAL CELLS DURING TUMOR GROWTH AND AFTER TUMOR LOSS. (E.) Halliday, W. J. (U. Washington Med. Sch., Seattle). *Cell Immunol* 3:113-112, 1972.

Sera and peritoneal cells (PC) were obtained from mice bearing primary Moloney virus-induced tumors or transplanted chemically induced tumors ("progressor" mice) and from mice in which these tumors had spontaneously regressed or had been surgically removed ("regressor" mice). No stimulus was given to produce peritoneal exudates. PC from the two types of tumor-treated animals were distinguishable. "Regressor" cells had their migration in culture inhibited by the corresponding soluble tumor antigen, whereas "progressor" cells did not. Mixtures of the two kinds of PC were not inhibited. "Progressor" PC produced a soluble substance *in vitro* which could block the normal inhibition of "regressor" cells. Sera from the two types of mice were also different. "Progressor" serum blocked the migration inhibition usually found with "regressor" PC. "Regressor" serum not only lacked this property but was able to unblock "progressor" PC, so that mixtures of the latter cells with this serum were inhibited by tumor antigen. Macrophage migration inhibition thus revealed cellular immunity and humoral factors analogous to those found by other techniques in animals and human subjects exposed to tumor antigens.

- 5975 METABOLIC ASPECTS OF LEUKEMIC LYMPHOCYTE IMMUNE REACTIVITY. (E.) Brody, J. I. (U. Pennsylvania Sch. Med., Philadelphia). *Acta Haematol* 47(3):129-133, 1972.

Leukemic lymphocytes cultured from seven patients with chronic lymphocytic leukemia were compared with lymphocytes from healthy donors to determine whether or not differences existed in their abilities to utilize glucose and to synthesize nucleic acid following exposure to phytohemagglutinin (PHA) and/or methylene blue (MB), two substances which stimulate glucose utilization via the Embden-Meyerhof (EM) pathway and hexose monophosphate (HMP) shunt, resp. As determined by the extent of formation of $^{14}\text{CO}_2$ and ^{14}C -labeled glycolytic intermediates by cells grown in ^{14}C -glucose-containing medium, leukemic lymphocytes showed a limited ability, compared with normal lymphocytes, to increase glucose metabolism when stimulated by PHA or MB alone or by PHA + MB. This limited

ability to enhance glucose metabolism by both the HMP shunt and the EM pathway was associated with a similar limitation in the ability to increase the incorporation of ^3H -thymidine into DNA following PHA and/or MB stimulation. These two phenomena appeared to be interdependent. These results suggest that the leukemic lymphocyte may react immunologically *in vivo* in a limited fashion which is determined by its inherent cellular metabolic deficiencies.

- 5976 STRUCTURAL STUDIES OF THE MAJOR GLYCOPROTEIN IN PREPARATIONS WITH CARCINOEMBRYONIC ANTIGEN ACTIVITY. (E.) Terry, W. D. (Natl. Cancer Inst., Bethesda, Md.), P. A. Henkart, J. E. Coligan and C. W. Todd. *J Exp Med* 136(1):200-204, 1972.

Amino acid sequence studies have been carried out on the only protein with an unblocked amino-terminal amino acid found in a carcinoembryonic antigen (CEA) fraction purified from colonic cancer metastases obtained from the livers of two patients. The amino acid compositions of the proteins from the two CEA fractions were very similar, with methionine being absent in both, and were very similar to the compositions obtained for CEA preparations from five other tumors. Sixteen of the first 19 residues of the one preparation and the first 24 residues of the second were determined and found to be identical. The finding of identical sequences in the CEA preparations from the two different tumors suggests that this polypeptide is probably the same in all fractions with CEA activity.

- 5977 EPSTEIN-BARR VIRUS-SPECIFIC IgM IN INFECTIOUS MONONUCLEOSIS, BURKITT LYMPHOMA, AND NASOPHARYNGEAL CARCINOMA. (E.) Banatvala, J. E. (St. Thomas Hosp. Med. Sch., London, England), J. M. Best and D. K. Waller. *Lancet* (7762):1205-1208, 1972.

Whole and fractionated sera from patients with infectious mononucleosis (IM), Burkitt lymphoma, and nasopharyngeal carcinoma were tested by the indirect immunofluorescence method for the presence of Epstein-Barr virus-specific antibody. A virus-specific IgM response could be detected in serum fractions from 7 of 8 IM patients from 7 to 70 days after the onset of symptoms. In the eighth patient virus-specific IgM could be detected for six months corresponding to the duration of her symptoms. In all patients, total whole serum IgM titers were highest between 5 and 20 days after the onset of symptoms. No detectable virus-specific antibody could be detected in sera from patients who had had heterophile-antibody-positive IM between 3 and 9 yr previously. EB virus-specific IgM could also not be detected in sera from six patients with nasopharyngeal carcinoma, in sera from three patients with differing stages of Hodgkin's disease, or in sera from nine patients (two untreated, seven treated) with Burkitt lymphoma. Total serum IgM concentrations were raised in patients with acute IM, but were

generally normal during convalescence. Patients with Burkitt lymphoma and nasopharyngeal carcinoma had slightly lower IgM levels than did healthy donors. Serum IgG levels were normal in all groups of patients.

- 978 CARCINOEMBRYONIC ANTIGEN IN WHOLE SERUM. (E.) MacSween, J. M. (Hall Inst. Med. Res., Victoria, Australia), N. L. Warner, A. D. Ankhurst and I. R. Mackay. *Br J Cancer* 26(5):356-60, 1972.

Sera from 51 healthy donors and 326 patients with various neoplastic and nonneoplastic diseases were tested for the presence of carcinoembryonic antigen (CEA) using a modified microradioimmunoassay technique. The new technique differs from those previously described in that it is performed on 0.025 ml of whole serum instead of 5 ml of perchloric acid-extracted serum. Using whole serum, blood CEA levels as little as 5 ng/ml could be detected as compared to 3 ng/ml for perchloric acid-extracted serum. Whole sera from 20 of 23 patients with localized colonic cancer and from all 21 with disseminated colonic cancer were positive for the presence of CEA. In addition, CEA was detected in sera from patients with other types of cancer especially breast and lung) and with diseases other than cancer (particularly liver cirrhosis and pancreatitis). Sera from 5 of 51 healthy donors contained CEA levels greater than 5 ng/ml.

- 979 SUPPRESSION OF ESTABLISHED FRIEND VIRUS LEUKEMIA BY STATOLON. IV. ROLE OF HUMORAL ANTIBODY IN THE DEVELOPMENT OF A DORMANT INFECTION. (E.) Wheelock, E. F. (Jefferson Med. Coll., Philadelphia, Pa.), S. T. Toy, N. L. Caroline, J. R. Sibal, M. A. Fink, P. C. L. Beverley and J. C. Allison. *J Nat Cancer Inst* 48(3):665-673, 1972.

BA/2 mice were inoculated with Friend leukemia virus (FV); postinoculation, infected mice were injected i.v. with 4 mg statolon, a double-stranded RNA-containing mycophag. The progression of virus-induced leukemia symptoms in statolon-treated and untreated FV-infected mice was observed. The splenomegaly response to FV leukemia was abolished by statolon; grossly enlarged spleen in statolon-treated infected mice regressed to normal size. Antibody responses of mice in which FV infection had been suppressed by statolon (FV carriers) were compared with antibody responses in mice in which overt leukemia developed in spite of statolon treatment (statolon-FV-leukemic mice). FV-carriers' sera and statolon-FV-leukemic sera produced equal amounts of hemagglutinating antibody. Isotopic antiglobulin tests, however, showed that only FV-carriers produced significant amounts of antibody which bound to FV-leukemic cells. FV-carrier serum contained FV-neutralizing antibody activity at a 1:40 dilution, while statolon-FV-leukemic sera possessed neutralizing activity at only a 1:10 dilution. In *in vitro*

tests for anti-FV-leukemia activity of sera, sera from FV-carriers completely inhibited leukemogenesis in mice inoculated with FV and FV-leukemic spleen cells; no antileukemic activity was seen in statolon-FV-leukemic sera. Antibody levels declined as FV-carrier mice aged and FV emerged from its dormant state to produce overt leukemia.

- 6051 RELATIONSHIPS BETWEEN ULTRASTRUCTURE AND BIOLOGIC FEATURES OF PIGMENTARY TUMORS (NEVUS CELL NEVI, MELANOSIS PROBLASTOMATOSA, MALIGNANT MELANOMA). (Ger.) Klug, H. (Humboldt U., Berlin, Germany) and Th. Thormann. *Arch Geschwulstforsch* 37(4):368-386, 1971.

Electron microscopic studies were performed on cells of junctional nevi (JN), lentigo malignant melanomas (MP), and malignant melanomas (MM) to elucidate the relationship between the ultrastructure of these cells and their degree of malignancy. Distinct structural differences were observed between JN and MP cells. Both tumor forms can be easily distinguished. Differences lie in the structure of melanosomes, the different number of melanosomes and the mitochondria in the cytoplasm and in the nucleoli. The melanosomes of JN cells, however, are morphologically identical with the melanosomes of normal epidermal melanocytes. The chromatin structure of the JN cell nuclei does not differ markedly from MP cells and manifests small membrane invaginations sporadically. The large number of melanosomes in MP cells and their spherical form is conspicuous. No distinct lamellar inner structure has been observed as yet in premelanosomes. The most obvious morphologic difference between JN and MM cells is the fine structure and size of the nucleoli, independent of their pigment-forming ability. The structures observed on MM cells clearly point to increased or disturbed RNA or protein synthesis in the tumor cells. Therefore, structure and size of nucleoli are reliable morphologic criteria of the degree of malignancy. The considerable difference in the number of mitochondria in JN and MM cells is another indicator of the different metabolic activity of both cell forms.

- 6052 MEMBRANE PROLIFERATION AND PHOSPHATIDYLCHOLINE SYNTHESIS IN NORMAL, PRENEOPLASTIC, AND NEOPLASTIC MAMMARY GLAND TISSUES IN C3H MICE. (E.) Hillyard, L. A. (Children's Hosp. Med. Ctr. Northern California, Oakland) and S. Abraham. *Cancer Res.* 32(12):2834-2841, 1972.

The rates of incorporation of uniformly labeled L-leucine- ^{14}C into protein and of choline-methyl- ^{14}C and L-methionine-methyl- ^{14}C into the phosphatidylcholine of the organelle membranes was determined for tissue slices prepared from normal mammary glands, preneoplastic hyperplastic alveolar nodule outgrowths, and mammary adenocarcinomas of C3H mice. The relative incorporation rates of uniformly labeled leucine- ^{14}C and of choline-methyl- ^{14}C were compared with the rate of incorporation of thymidine-methyl- ^3H into the DNA of each tissue. The rate of membrane protein synthesis as indicated by the leucine incorporation rate did not correlate with cell growth, since synthesis in the rapidly growing mammary glands in pregnant mice was not significantly greater than that in the slower growing mammary glands in lactating mice. The observations were made that methylation of phosphatidylethanolamine did not contribute to phosphatidylcholine synthesis and that the correlation between choline-methyl- ^{14}C and thymidine-methyl- ^3H incorporation in the various

mammary gland tissues was good. These findings suggest that choline incorporation into phosphatidylcholine has general applicability to studies on membrane proliferation in mammary glands. Subcellular fractions from each mammary tissue were assayed for activities of phosphodiesterase I and NADPH-cytochrome *c* reductase enzymes localized in the endoplasmic reticulum. NADPH-cytochrome *c* activity in the hyperplastic alveolar nodule outgrowth was similar to that in normal lactating gland rather than that in the histologically identical normal gland of pregnancy. The intracellular distribution of NADPH-cytochrome *c* activity in the mammary adenocarcinoma suggests that homogenization of this tumor produces particles, derived from the endoplasmic reticulum, with a density distribution different than that produced from normal tissue.

- 6053 THE IMPORTANCE OF HYPOXIA IN PATHOGENESIS OF NEOPLASMS. (Rus.) Belousov, A. P. (P. A. Gertsen Res. Inst. Oncol., Moscow, USSR), S. D. Pletnev, M. K. Kochetkov, L. D. Ostrovtshev and E. B. Mairanovskaya. *Vopr Onkol* 18(5):12-16, 1972.

The intensity of hypoxia in neoplastic and normal tissues of the mammary gland was studied in 177 patients with cancer and mastopathy of the mammary gland (including 68 with breast cancer) and 15 healthy women. The oxygen flow in tissues was determined by means of a polarographic method using an open electrode introduced into the tested tissue and connected with a recording device; another electrode was applied to the skin surface. Oxygen flow data were expressed in mg of O_2 passed through a one cm^2 section per second, referred to as oxygen index. Two groups were distinguished according to the intensity of the oxygen flow data. The first group, with a low oxygen flow index consisted of 132 persons with a median oxygen index of 0.78-0.92 mg/ cm^2 sec (patients) and 1.12 mg/ cm^2 sec (normal subjects). The second group, with a high oxygen flow index of 1.65-2.39 in patients and 2.32 mg/ cm^2 sec in healthy subjects included 60 people. Thirty percent of the first group and 46% of the second group were cancer patients. The intensity of oxygen flow was significantly decreased in the (normal) intact tissue of 68% of the patients with mastopathy, cyst, fibroadenoma, and cancer of the mammary gland. The oxygen flow was relatively high and no hypoxia was seen in normal tissue of 32% of the patients. Hypoxia was ascertained in all neoplastic tissues indicating that neoplasia of the mammary gland develops in a background of local tissue hypoxia.

6073 LEUKEMIA INCIDENCE IN SAMARKAND AND THE SAMARKAND REGION IN 1966-1969. (Rus.)

Bogdanov, I. S. (Uzbek Inst. Hematol. Blood Transfusion, Tashkent, USSR) and Kh. A. Khakimov. *Probl Gemat Pereliv Krovi* 17(2):33-34, 1972.

The incidence of leukemia in the Samarkand region, the center of agriculture and industry of Uzbekistan USSR, was studied. A total of 264 patients with various forms of leukemias and hemoblastoses was recorded in this region in 1966-1969. The incidence of leukemias and hemoblastoses to the total incidence of diseases was 0.048% and that to total oncological diseases was 7.84%, being fourth among malignancies after carcinoma of the stomach, skin, and esophagus. The mean annual incidence of leukemias and hemoblastoses in cities and rural areas for 1966-1969 was 4.81 per 100,000 population. The mean annual index of incidence of leukemias and hemoblastoses was 8.94 in the cities and 3.73 in the rural areas. The mean annual incidence index was different according to the types of leukemias. Of 18 cases of chronic lympholeukemia in the Samarkand region in 1966-1969, only one case was seen in the rural area, while 17 cases were seen in cities. The mean annual index of incidence of chronic lympholeukemia for the period 1966-1969 was 0.33/100,000 residents (1.22 in cities). The male/female ratio was 1.3:1. There were 94 cases of acute forms of leukemia (1.71/100,000 population). Of these, 49 cases were lymphogranulematoses (0.87/100,000 population). The mean annual index for the total incidence of leukemia and hemoblastoses was 8.54/100,000 population. Chronic forms of leukemia were most prevalent, being 3.32/100,000, followed by acute forms (3.06/100,000).

6074 HODGKIN'S DISEASE: CASES WITH FEATURES OF A COMMUNITY OUTBREAK. (E.) Vianna, N. J.

(New York State Dept. Hlth., Albany), P. Greenwald, J. Brady, A. K. Polan, A. Dwork, J. Mauro and J. N. P. Davies. *Ann Intern Med* 77(2):169-180, 1972.

A study of the incidence of Hodgkin's disease in Albany County, N.Y., from 1950 through 1970, showed a period of high incidence followed by an apparently reciprocal period, when the incidence of the disease was below average. The increased incidence closely paralleled temporally the occurrence of cases in a specific group of students, their friends, and household relatives. Thirty-four lymphoma cases, of which 31 were Hodgkin's disease, have been interlinked to date. These observations and the occurrence of similar Hodgkin's disease groupings in two different areas suggest that the pattern of disease occurrence was similar to that of an infectious disease.

6075 CANCER MORTALITY AMONG U.S. JEWS. (E.) Haenszel, W. (Nat'l. Cancer Inst., Bethesda, Md.). *Israel J Med Sci* 7(12):1437-1450, 1971.

Cancer Registry data from the U.S. were reviewed to determine the relative position of the risks for Jews when contrasted with non-Jewish populations.

Sex differences were found for the incidence of tumors of all sites except the G.I. tract. Males generally had low risks for cancers of the buccal cavity, pharynx and prostate whereas Jewish female risks were similar to those of the general non-Jewish population. Females showed a decreased incidence of carcinomas of the cervix and bladder and an increased incidence of cancers of the esophagus (foreign born only), pancreas, lung, breast (U.S. born), ovary and excess leukemia and lymphomas compared with other U.S. white populations. In general, however, the pattern of site-specific risk of U.S. Jews was similar to that of other white U.S. populations. The male:female sex ratios of site-specific risks among U.S. Jews were generally lower than for other U.S. white populations. Comparisons of the U.S. data with those from Israel's Cancer Registry suggest that these lower sex ratios of risk were characteristic of Jews in both countries.

6076 CANCER MORTALITY IN THE DISTRICT OF SKOPJE FROM 1961 TO 1969. (E.) Gjorgov, A.

(Municipal Public Hlth. Inst., Skopje, Yugoslavia). *Lijec Vjesn* 93(5):517-532, 1971.

A retrospective study of the incidence of all types of cancer was conducted in the district of Skopje, Yugoslavia, for the years 1961 to 1969. Data were obtained from death certificates, card indices and from official reports of the Central Statistics Office of Skopje. From 1961 to 1969, 1093 men and 838 women died of cancer in Skopje (population about 370,000). Although the overall morbidity rates in rural and urban areas were approximately the same, nearly three times as many urban dwellers as rural inhabitants died of their disease. The annual rate of increase in the incidence of cancer was much higher (9.8%) for immigrants to the area than for either urban natives (3.5%) or the rural population (2.3%). Deaths due to cancer were also much higher in the immigrant population. The large annual increases could be attributed both to improved records and to an actual increase in the number of cases. The annual rate of increase in fatal cancer cases was greatest (7.7%) for people older than 65 yr, followed by the 25 to 44-yr-old age group (6.6%) and by people under 25 yr of age (2.8%). The principal cause of death for both sexes was gastric carcinoma. Pulmonary cancer was the second leading cause of death in men and cancer of the reproductive tract was the second leading cause in women. The highest annual rate of increase (16.5%) was in female gastric cancer followed by cancer of the female reproductive organs (9.5%) and pulmonary cancer in men (8.7%).

6077 THE KINETICS OF CELLULAR PROLIFERATION IN NORMAL AND MALIGNANT TISSUES. NUCLEIC ACID METABOLISM IN RELATION TO THE CELL CYCLE IN HUMAN TISSUES. (E.) Fabrikant, J. I. (Dept. Radiological Sci., Johns Hopkins U., Baltimore, Md.), M. J. Vitak and C. L. Wissemann, III. *Growth* 36(3):173-183, 1972.

The kinetics of tumor cell proliferation in normal and diseased tissues of the human larynx have been examined in patients using nucleic acid precursor labeling techniques combined with high resolution autoradiography. The potential tissue doubling times based on cell phase distribution models have been determined in normal, inflammatory, and neoplastic lesions in 58 patients with diseases of the larynx and hypopharynx. The data are based on analyses of cell kinetic parameters, including pulse-labeling, and on tritium-, carbon-14-thymidine double-labeling techniques, on cell age models, and are corrected for the growth fraction and cell loss factor. They indicate that (1) the range of tissue doubling times for the normal epithelial mucosa of the human larynx is ~ 6 to 10 days; (2) values for carcinoma of the larynx are slightly longer than normal values; (3) inflammatory lesions have the fastest turnover rates; (4) the growth rates of benign tumors vary widely; and (5) the duration of DNA synthesis in human cells ranges from ~ 10 to 25 hours. Analysis of cell and tissue kinetics suggests that proliferation rates in neoplastic cells may not necessarily be greater than the normal cell populations from which they arise. The *in vitro* techniques have also been adapted to examine the incorporation of tritiated uridine to study RNA synthesis in human tissues. The relationships of nucleic acid metabolism and cell population kinetics are discussed in terms of cellular control mechanisms and growth characteristics of neoplastic tissues in man, and the observations are related to the implications of tumor cell proliferation in the clinical situation.

6078 EPIDEMIOLOGY OF HODGKIN'S DISEASE. (E.)
Cole, P. (Harvard Sch. Public Hlth.,
Boston, Mass.). *JAMA* 222(13):1636-1639, 1972.

The two major current issues in the epidemiology of Hodgkin's disease are 1) the nature of the disease and 2) the specific etiology of the disease. The age-incidence curve of Hodgkin's disease is bimodal. In younger patients, the incidence is only slightly higher in males than females, there is no association with any religious group, and at diagnosis the disease is usually localized. The histologic patterns are those associated with a more favorable prognosis. In patients over 50 yrs of age, Jewish males predominate, the disease is usually disseminated, and the histologic patterns are those associated with a poor prognosis. Current evidence, which is often contradictory, tends to favor the concept that Hodgkin's disease is two processes, each with a distinct etiology. However, the possibility that the heterogeneous nature of the disease is due to variations in host response to a single etiologic factor cannot be eliminated. With respect to young people, a moderate amount of circumstantial evidence supports a specific viral etiology for Hodgkin's disease. It has also been suggested that tonsillectomy places young people into a higher risk group with respect to Hodgkin's disease. However, results have indicated that some uncontrolled variable, rather than tonsillectomy itself, may account for the association.

6079 CANCER OF THE ESOPHAGUS IN CENTRAL AFRICA.
(E.) Wapnick, S. (Ichilov Hosp., Tel Aviv, Israel), L. N. D. Zanamwe, M. Chitiyo and J. M. Mynors. *Chest* 61(7):649-654, 1972.

Data on Africans with esophageal cancer admitted to Harari Hospital, Salisbury, Rhodesia, between 1958-1970 were reviewed. Out of a total of 404 cases of cancer of the esophagus 333 cases were squamous carcinomas and four were adenocarcinomas. Forty-two percent of patients were from Malawi, 20% were from Mozambique and 38% were from Rhodesia. The relatively high percentages of hospital admissions from other African states may explain the unusually high esophageal cancer rate recorded in Rhodesia. Ninety-eight percent of patients were males, and a slight excess of blood group A persons was seen in the patient group. African patients with esophageal cancer presented at a younger age than that reported for white patients. Various etiological factors for esophageal cancer in Africans are discussed, including the drinking of liquors made in pots which contain carcinogens.

6080 RACIAL AND SOCIOECONOMIC FACTORS IN COLONIC CANCER SURVIVAL. (E.) Krain, L. S. (U. California Los Angeles Med. Ctr.). *Ann Surg* 175(4):601-606, 1972.

Data on incidence and mortality from colonic cancer compiled by the California Tumor Registry were analyzed for socioeconomic and racial patterns in colonic cancer survival. Socioeconomic level was ranked from high to low, on a four-point scale, according to criteria of income, education and employment. Nonwhites had higher incidence and poorer survival rates for colonic cancer than whites. Colonic cancers in nonwhites were more apt to be in an advanced stage at diagnosis than colonic cancers in whites. The incidence of colonic cancer in California was found to be rising, and to be significantly higher in the two higher socioeconomic counties. However, there were no significant differences in the localization of colonic cancers (i.e., cecum, appendix, ascending or transverse colon, or sigmoid colon) between different socioeconomic or racial groups.

6081 A COMPARATIVE MORPHOLOGIC STUDY OF ROUS RAT SARCOMA WITH NORMAL AND ABNORMAL CHROMOSOMAL PATTERN. (E.) Lindberg, L. G. (Inst. Path., U. Lund, Sweden), F. Mitelman and P. Vorwerk. *Lab Invest* 27(4):387-392, 1972.

Morphologic and volumetric data of Rous rat sarcoma cells with normal diploid karyotype are compared with the same data obtained from a Rous rat sarcoma with cells containing four extra chromosomes. Primary Rous rat sarcoma (RR sarcoma) was transplanted to succeeding generations of rats and chromosomes were studied intermittently, usually every other passage. Preparations for electron microscopic studies were selected from passages 1 and 14, resp. In passage 1, as in the primary sarcoma, 100% of

the tumor cells analyzed had a normal diploid karyotype whereas in passage 14 no cells with a normal karyotype were observed; the stemline number was 46 and differed from the normal by gains of $2t$, $1st_3$ and $1st_5$ chromosome. RR sarcomas were composed of two morphologically different types of cells: a large cell with much cytoplasm and a nucleus containing scanty granular chromatin and a large nucleolus (A cells); and a small cell with a proportionally large nucleus and dense chromatin pattern (C cells). Karyologically normal RR A cells were 60% larger than karyologically abnormal A cells, while aneuploid C cells were twice as large as diploid C cells. Other parameters common to RR cells did not differ between the diploid and non-diploid cells.

- 6082 THE DISTRIBUTION OF CANCER WITHIN THE LARGE BOWEL. (E.) De Jong, U. W. (Epidemiol. Biostatistics U., IARC, Lyons, France), N. E. Day, C. S. Muir, T. H. C. Barclay, G. Bras, F. H. Foster, D. J. Jussawalla, M. Kurihara, G. Linden, I. Martinez, P. M. Payne, E. Pedersen, N. Ringertz and T. Shammugaratnam. *Int J Cancer* 10(3):463-477, 1972.

The incidence of large-bowel cancer by subsites of the colon and rectum was determined for 13 populations: Alameda County (California), Bombay, Denmark, Kingston and St. Andrew (Jamaica), Miyagi Prefecture (Japan), New Zealand, Norway, Puerto Rico, Saskatchewan (Canada), Singapore, Southern Metropolitan Cancer Registry (England) and Sweden. In this series, the highest rates for large-bowel cancer are found in North America and New Zealand and the lowest in the East (Japan, Bombay and Singapore) and the Caribbean. Intermediate rates prevail in Scandinavia and England. In areas of high and intermediate risk, the incidence of large-bowel cancer decreases from ascending colon toward the descending colon with a sharp increase in incidence at the sigmoid colon, the rates for the rectum being in turn higher than those for the sigmoid. In low-incidence areas, the general pattern is the same, but there may be a deficit of sigmoid cancers. Denmark has a significant excess of low rectum cancer, particularly in males, although the rates for other parts of the large intestine in this registry are in the intermediate range. Under age 65 yr the sex ratio for each registry is fairly uniform throughout the colon. At age 65 and over, the incidence of descending and sigmoid colon cancer increases more steeply in males than in females, as does the incidence of rectal cancer. The sex ratios for ascending and transverse colon cancer do not change with advancing age. The results are consistent with subsite risk being related to the transportation rate of colonic content. Rates in a variety of risk situations need to be investigated, with particular attention to the sigmoid in low-risk areas.

- 6083 INCIDENCE OF NEOPLASMS IN CHILDREN BORN AFTER INFLUENZA EPIDEMICS. (E.) Leck, I. (Dept. Social Preventive Med., U. Manchester, England) and J. K. Steward. *Brit Med J* 4(5841): 631-634, 1972.

The hypothesis that children whose mothers have had influenza during pregnancy are especially susceptible to lymphatic and hematopoietic tumors was tested. The incidence of such tumors among children registered at the Manchester (England) Children's Tumor Registry between 1954-1968 was studied. Six influenza epidemics had occurred in the Manchester area during the study period. The incidence of lymphatic and hematopoietic tissue neoplasms was no higher among children born after these epidemics than among children born at other times.

- 6084 PETS AND ADULT LEUKEMIA. (E.) Bross, I. D. J. (Roswell Park Mem. Inst., Buffalo, N.Y.), Sister R. Bertell and R. Gibson. *Am J Pub Health* 62(11):1520-1531, 1972.

Data on leukemia incidence in adults in the Tri-State Survey (New York, Maryland and Minnesota) were compiled and correlated with exposure to pet animals. A total of 1413 leukemia cases (with appropriate controls) was studied between 1959 and 1962. When correlations were sought between leukemia incidence and exposure to animals without regard to the health of the animals in question, results were negative. However, exposure to sick cats increased the leukemia risk from 1.09 for all cats to 1.75, and exposure to sick birds increased the risk from 1.26 with all birds to 1.99. Evidence for a correlation between leukemia and exposure to sick dogs was equivocal. The effect of sick pets showed more strongly in patients with acute as opposed to chronic leukemia. The largest risk for exposure to sick birds and cats was seen for acute lymphatic leukemia.

- 6085 EPIDEMIOLOGIC STUDIES ON UTERINE CANCER AT CANCER INSTITUTE HOSPITAL, TOKYO, JAPAN. (E.) Masubuchi, K. (Cancer Inst. Hosp., Tokyo, Japan) and H. Nemoto. *Cancer* 30(1):268-275, 1972.

Five hundred seventy-two female patients with uterine carcinoma and 200 randomly chosen noncancer patients seen at the Cancer Institute Hospital, Tokyo, Japan, were interviewed in an epidemiological study. In addition, the hospital records of 2,923 patients with uterine carcinoma treated in the clinic from 1954-1963 were examined and compared with the records of 100 randomly chosen noncancer patients seen during the same period. Patients with carcinoma of the corpus or cervix were married at a younger age than the women from the control groups. Women with cervical carcinoma had more pregnancies and deliveries, were younger at the time of their first delivery and were older at the time of their last delivery than were the women of the control groups. Significantly more women with corpus carcinoma were nulliparous than were women of the control groups. The percentage of carcinoma patients who had first intercourse before the age of 19 was higher than that of the control groups. The proportion of patients with either a history of syphilis or a positive Wassermann test at the time of admission was higher in the carcinoma groups than

in the controls. The proportion of carcinoma patients whose spouses had a history of phimosis or paraphimosis was greater than that of the control group. The data also suggested a familial tendency for uterine and extra-uterine carcinoma; however, these results were not statistically different from the controls.

- 6086 SOME OBSERVATIONS ON THE EPIDEMIOLOGY OF CANCER OF THE BREAST IN WOMEN OF WESTERN INDIA. (E.) Paymaster, J. C. (Tata Mem. Hosp., Bombay, India) and P. Gangadharan. *Int J Cancer* 10(3):443-450, 1972.

Cancer of the cervix is the most common cancer in Indian women followed by cancer of the breast. Between 1941-1970, 65% of the women cancer patients at Tata Memorial Hospital, Bombay, had cancer of the cervix (28,865 cases) and 30% had breast cancer (7409 cases). The incidence of breast cancer varied widely among females of different religious communities and was highest among Parsis (49.4%) and Sindhis (30.5%). A comparison of 746 cancer cases with 746 controls suggested that factors such as age at marriage, age at first pregnancy, and number of children are high-risk factors in the etiology of cancer in patients between 40-54 yr of age. Almost 80% of the Parsi women with breast cancer were age 45 or above. Compared with other communities, the proportion of never married women is high among Parsis. A trend to late age at first marriage has resulted in increased age at first pregnancy and low total parity.

- 6087 CANCER MORTALITY IN NEW ZEALAND: 4. OTHER PRIMARY SITES. (E.) Donovan, J. W. (Dept. Math. Stat., U. Sydney, Australia). *NZ Med J* 75(478):144-148, 1972.

New Zealand cancer statistics from 1941 to 1968 were reviewed to determine mortality trends for cancers of the lung, kidney, bladder; leukemias; and some less common cancers. Increases in lung cancer mortality were found to have declined among younger male cohorts, though Maori males and females continued to show very high lung cancer death rates, the rate for Maori females being three times the highest national rate given in a recent report. Kidney cancer mortality did not change over the study period. Bladder cancer deaths increased in males over 65, and leukemia deaths increased among both males and females for persons over 75. The latter increase may have been due to increased diagnosis of leukemia, though a real increase in stem cell leukemia was indicated. Laryngeal cancer mortality was on the decline in New Zealand. Malignant melanoma mortality and brain tumor mortality were on the rise. Bone cancer deaths were decreasing, perhaps because of fewer false diagnoses.

MISCELLANEOUS

6108 COMPARATIVE CYTOGENETIC AND QUANTITATIVE
CYTOCHEMICAL DNA STUDIES IN ACUTE LEUKEMIAS.
(Ger.) Müller, D. (Med. Clin., Inst. Anthropol.
Human Genetics, U. Tübingen, West Germany), D. Orywall
and N. Hübner. *Blut* 23(5):287-301, 1971.

A comparative study of cytogenetic and cytochemical
findings in 15 cases of acute leukemia was conducted.
The overwhelming number of metaphases appearing in all
the well growing preparations indicated the presence
of diploid chromosomes. In 13 of these patients, a
cell frequency of 32-36 arbitrary units could be de-
tected by Feulgen photometry which corresponded to
previously determined figures on normal bone marrow
granulocytes. One patient with myeloblastic leu-
kemia exhibited a hyperdiploidy with 53 chromosomes,
together with a Feulgen photometric increased
DNA value, which was proportional to the increase
in chromosomes. Another patient with myeloblastic
leukemia showed numerous tetraploid metaphases in
the chromosome analysis. In four leukemia patients
increased blasts were demonstrated with a twofold
increase in DNA. No correlation could be detected
between DNA values of a blast population and
the aberrations in chromosome counts. Other factors
may be involved in determining the DNA content of
leukemia blasts, besides chromosome quantities.

6109 REGULATION OF THE NUCLEOLAR DNA-DEPENDENT
RNA POLYMERASE BY AMINO ACIDS IN EHRlich
ASCITES TUMOR CELLS. (E.) Franze-Fernandez, M. T.
New York Blood Ctr., New York) and A. O. Pogo.
Proc Nat Acad Sci USA 68(12):3040-3044, 1971.

Amino acids in incubation media are thought to be
regulatory factors controlling nucleolar RNA polymer-
ase activity. RNA polymerase was assayed by measur-
ing the incorporation of [³H]GMP and [³H]UMP into
RNA. Ehrlich ascites tumor cells of mice were in-
cubated with and without added amino acids in Eagle's
medium. [³H]uridine incorporation into 45S rRNA
showed more labeled 45S rRNA in amino acid-enriched
cells than in cells from low amino acid media. Cells
incubated with or without amino acids had similar
amounts of [³H]uridine incorporated into RNA species
other than the 45S rRNA. RNA polymerase assay was
inhibited by actinomycin D, thereby showing its DNA
dependence. In nuclei of cells from amino acid-
enriched media, GMP incorporation into RNA was
consistently high. Kinetics of GMP incorporation
show a similar time course in both high and low
amino acid media, yet the rate of GMP incorporation
and final plateau level were less in cells from low
amino acid media. Cells exposed to a medium of high
amino acid concentration show a rapid rise in enzyme
activity leveling off at 20 min; a second burst of
activity was detected after 60 min. The non-linear
enzyme activity elevations suggest that more than
one metabolic process may be involved in controlling
the activity of nucleolar RNA polymerase.

6110 MULTIPLE CHROMOSOME ABERRATIONS IN A LYMPHO-
SARCOMATOUS TUMOR. (E.) Fleischmann, T.

(Inst. Genetics, U. Lund, Sweden), C. H. Hakansson,
A. Levan and T. Möller. *Hereditas* 70(2):243-258,
1972.

Karyotype studies were performed on material from
two biopsies taken from a fatal lymphoblastic sar-
coma developed on a 61-yr-old man. The chromosome
number 48 predominated in chromosome fixations from
both biopsies. The stemline appeared to have changed
in the proportions of the normal chromosome types.
The most striking change observed, however, was the
appearance of five medium-sized marker chromosomes
with a completely median centromere. These chromo-
somes showed up on orcein slides and fluorescence
analysis of chromosomes. Though two of these
marker chromosomes appeared to be fragments of other
chromosomes, three remained unexplained. These three
markers fluoresced brightly and evenly in both arms.
They resembled markers recently found in four other
malignant lymphomas.

6111 ENDOCRINE STUDIES IN POST-MENOPAUSAL WOMEN
WITH OVARIAN TUMOURS. (E.) Edwards, R. L.
(Birmingham Midland Hosp. Women, England), H. O.
Nicholson, T. Zoidis, W. R. Butt and C. W. Taylor.
J Obstet Gynaecol Br Commow 78:467-477, 1971.

An endocrine assessment was made in 78 post-menopau-
sal women. The urinary excretion of estriol was
greater than 10 µg per 24 hours in 14 out of 31
cases with malignant ovarian tumors, in 2 out of 24
cases with benign ovarian tumors, and in 6 out of 23
cases without ovarian tumors. Although the urinary
estriol excretion was increased in all eight cases with
mucinous carcinoma it was raised in only 4 out of 18
cases with serous carcinoma. Some of the greatest
amounts of urinary estriol were found in cases with-
out ovarian tumors. The urinary excretion of
pregnanediol was increased in 6 out of 18 cases.
These six patients also had increased estriol excre-
tion. The excretion of steroids was normal after
oophorectomy. Tests of adrenal cortical activity and
ovarian vein blood analysis also point to the
diseased ovary as the site of increased steroid
synthesis. The correlation of increased urinary
estriol with vaginal cornification index was fair,
but with vaginal bleeding and endometrial activity
was poor.

6112 STUDIES ON PLASMA MEMBRANES. XVII. ON
THE CHEMICAL COMPOSITION OF PLASMA MEM-
BRANES PREPARED FROM RAT AND MOUSE LIVER AND HEPA-
TOMAS. (E.) Emmelot, P. (Netherlands Cancer Inst.,
Amsterdam) and C. J. Bos. *J Membrane Biol* 9(1):83-
104, 1972.

Plasma membranes were isolated under hypotonic
conditions from rat and mouse livers and five hepato-
mas, i.e. one rather anaplastic rat hepatoma (and
its subline) and three well-differentiated mouse
hepatomas. All these membranes contained some 25%
protein soluble in 0.15 M NaCl. Evidence is pre-
sented that this protein is mainly, if not exclusively

of nonmembranous origin. Protein/phospholipid P (P=phosphorus) ratios did not differ significantly for the various plasma membrane species except the rat-hepatoma subline, which showed a markedly lower ratio and was thus identified. Hepatoma membranes contained more P of a nonphospholipid nature than did liver membranes and to this increase contributed in all instances an increased RNA content and in some cases also an increased DNA content. RNA may be present in isolated plasma membranes in two forms: one type that cannot be removed and another that is removable by physiological saline. The saline-soluble type of membrane RNA results from the presence of Ca^{2+} during homogenization and is a low molecular wt RNA species that could be transfer RNA of the cytoplasm. Whether the RNA of the saline-insoluble membranes, which corresponds in amount to about 1% of the clean-membrane protein on a weight basis, is a genuine constituent of the plasma membranes, remains to be established. The increase in hepatoma-membrane RNA is attributed to the ribosomal RNA of the few microsomal vesicles which are structurally connected with these plasma membranes. The sialic acid content and the percentage of neuraminidase-resistant sialic acid of hepatoma as compared with liver membranes was either similar or changed, depending on the hepatoma strain. Gel-filtration of trypsin-released peptides of liver plasma membranes showed hexosamine and hexose to be confined to the sialic acid-containing fractions. In spite of quantitative differences among fractions, the relative contents of the three carbohydrates in the combined fractions were (about) similar to those in intact liver membranes. Similar experiments with the rat-hepatoma membranes showed a changed carbohydrate expression.

- 6113 RENAL CARCINOMA (HYPERNEPHROMA) OCCURRING IN 5 SIBLINGS. (E.) Franksson, C. (Serafimer Hosp., Caroline Inst., Stockholm, Sweden), A. Bergstrand, I. Ljungdahl, G. Magnusson and H. Nordenstam. *J Urol* 108:58-61, 1972.

Primary renal carcinoma has been demonstrated in five siblings. The tumors were multiple and bilateral in four of the patients and located in the right kidney of the other. The clinical picture and histologic patterns were consistent in all five cases. Symptoms first appeared when the patients were between 37 and 53 yr old and included fever, hematuria, backache, and a palpable tumor. All tumors were well demarcated from the renal tissue and from the perirenal and hilar fatty connective tissue. Both the primary tumors and the metastases consisted histologically of tubular or papillary structures with a poorly developed connective tissue matrix. One patient with bilateral tumors had a history of polycystic kidneys.

- 6114 CYCLIC 3',5'-NUCLEOTIDE MONOPHOSPHATE PHOSPHODIESTERASE ACTIVITY IN HEPATOMAS OF DIFFERENT GROWTH RATES. (E.) Rhoads, A. R. (Howard U. Coll. Med., Washington, D.C.), H. P. Morris and W. L. West. *Cancer Res* 32(12):2651-2655, 1972.

Cyclic 3',5'-nucleotide monophosphate phosphodiesterase activity was determined for seven hepatomas of different growth rates and host livers. Activity was measured in the soluble fraction of the cell ($78,000 \times g$) in the presence and absence of 4 mM imidazole. The activity of phosphodiesterase in all hepatomas examined was significantly below the level found in normal liver of non tumor-bearing rats. This decrease level of phosphodiesterase activity was observed in both the presence and absence of imidazole and ranged from 30 to 60% of levels found in respective controls. The enzyme from neoplastic tissue showed a decreased response to imidazole stimulation. At 40 mM, imidazole caused an average stimulation of 28% for normal and host liver tissue compared to 16% for the enzyme from hepatomas. Decreased phosphodiesterase activity was also observed in the host livers of animals bearing hepatoma 7800 and 7777. In contrast to decreased activity in hepatomas, fetal liver and regenerating liver showed a significant increase in the imidazole-stimulated activity. In the presence of imidazole, phosphodiesterase activity in all tissues was stimulated 110 and 135% of basal levels. Differences in the pH-activity profiles were observed between phosphodiesterase from normal and neoplastic liver. Phosphodiesterase of normal liver had a well-defined pH optimum at 7.4, whereas the activity from hepatoma had a broader optimum ranging from 6.2 to 7.4. Kinetic plots of the hydrolysis of cyclic adenosine 3',5'-monophosphate exhibited anomalous behavior suggesting that both normal and neoplastic tissue contain at least two different phosphodiesterase activities. Apparent Michaelis constants for the high- and low-affinity enzymes ranged from 2.5 to 7.6 μM and from 39 to 54 μM , respectively.

- 6115 STUDIES ON PLASMA MEMBRANES. XVIII. LIPID CLASS COMPOSITION OF PLASMA MEMBRANES ISOLATED FROM RAT AND MOUSE LIVER AND HEPATOMAS. (E.) Hoeven, R. R. van (Netherlands Cancer Inst., Amsterdam) and P. Emmelot. *J Membrane Biol* 9(2):105-126, 1972.

Plasma membranes were isolated from homogenates of normal mouse and rat livers, of two slowly growing and well-differentiated mouse hepatomas and of one anaplastic and rapidly growing rat hepatomas (and its subline), and their lipid class compositions were chemically determined and compared. Total lipids accounted for 30-35% of the dry wt of the membranes of normal rat and mouse livers and of the mouse hepatomas, and for 45% in the rat hepatoma subline. Phospholipids accounted for 60, 55, and 50% of the total lipid fraction of normal rat liver, normal mouse liver and rat hepatoma, and of mouse hepatoma membranes, resp. In all plasma cell membranes studied, cholesterol was the major neutral lipid. Both rat and mouse hepatoma membranes contained 25-50% more cholesterol than did normal liver membranes. Although cholesterol esters of hepatoma membranes were increased, the differences in the cholesterol contents were probably due to increases in the free cholesterol fraction. Increases were also observed in the free fatty acid content of the

mouse and rat hepatoma membranes. The major phospholipid components of all plasma membranes studied were phosphatidyl choline, sphingomyelin, phosphatidyl ethanolamine and phosphatidyl serine. Their relative proportions differed appreciably, with normal mouse and rat liver membranes showing the closest resemblance. Cardiolipin was absent from normal rat and mouse liver membranes, but could be detected in hepatoma membranes due to mitochondrial contamination. No consistent phospholipid profile characterized the hepatomas as opposed to normal liver plasma membranes, nor did the profiles (including plasmalogens) resemble those previously reported for other hepatomas. The only distinguishing feature appeared to be the increased cholesterol levels of the hepatoma plasma membranes.

- 6116 SPECIFIC ESTROGEN-RECEPTORS IN THE NEOPLASTIC AND LACTATING MAMMARY GLAND OF THE RAT. (E.) Wittcliff, J. L. (U. Rochester Sch. Med. Dentistry, N.Y.), D. G. Gardner, W. L. Battema and P. J. Gilbert. *Biochem Biophys Res Commun* 48(1):119-125, 1972.

Specific ^3H -estradiol- 17β receptors were studied by a sucrose gradient assay of cytosol fractions from homogenates of normal lactating mammary gland and the estrogen-responsive R3230AC rat mammary adenocarcinoma. Specific estrogen-binding substances, sedimenting as 8S particles, were detected in both normal lactating breast and mammary adenocarcinoma. Preincubation of the cytosol fractions with the antiuterotropic substance CN-55, 945-27 prevented binding of ^3H -estradiol. The 8S receptors of both tissues were saturated at estradiol concentrations of 1-2 nM. The estrogen receptors in the hyperplastic and neoplastic tissues exhibited similar dissociation constants of approximately 1×10^{-9} M. Lactating mammary gland contained about three times as many receptors per mg protein as the mammary adenocarcinoma. Ovariectomy of the host had no apparent effect on the number of binding sites per mg protein in the R3230AC tumor. Progesterone, hydrocortisone, testosterone and dihydrotestosterone did not bind to the estrogen receptors of either lactating mammary gland or R3230AC tumor.

- 6117 FAMILIAL ACUTE MYELOID LEUKAEMIA WITH ACQUIRED PELGER-HUET ANOMALY AND ANEUPLOIDY OF C GROUP. (E.) Kaur, J. (Royal Postgrad. Med. Sch., London, England), D. Catovsky, H. Valdimarsson, J. Jansson and A. S. D. Spiers. *Brit Med J* (5836):327-331, 1972.

An Icelandic family is described in which all five members of a sibship had leukemia; two members had acute myeloid leukemia, one had myelofibrosis and leukemic change, and two had evidence of preleukemia. The acquired form of the Pelger-Huët and anomaly was seen in neutrophils of all siblings. Also, bone marrow cells showing aneuploidy of the C group chromosomes (chromosome number = 47) were seen in two sibs. Immunological deficiencies and increased

susceptibility to virus infection were also present in the family.

- 6118 INDUCTION OF MELANOTIC PSEUDOTUMORS IN *DROSOPHILA MELANOGASTER* BY JUVENILE HORMONE. (E.) Madhavan, K. (Lab. Develop. Biol., Swiss Federal Inst. Technol., Zürich). *Wilhelm Roux Arch* 169(4):345-349, 1972.

Larva, prepupae and pharate adults of *Drosophila melanogaster*, strains *aldehyde oxidase negative* (*Aldoxⁿ*), *bw*, *yv* and *yvf*, were given topical applications of Cecropia C_{18} juvenile hormone (JH) dissolved in N,N-dimethylformamide (DMFM). DMFM alone induced melanotic masses in 13% of *Aldoxⁿ* and *bw* third instar larva, but failed to induce masses in third instar *yv* or *yvf* larvae. JH induced melanotic masses in all strains tested, and produced masses in 100 and 79% of third instar *Aldoxⁿ* and *bw* larva, resp. Melanotic masses became macroscopically visible 26-32 hr after JH treatment. *Aldoxⁿ* and *yvf* larva, injured cutically before JH and/or DMFM, developed melanotic masses similar to those induced in uninjured larva by these agents. DMFM induced melanotic masses in 15% of late second instar *Aldoxⁿ* and *bw* larva; JH induced melanotic masses in 85% of late second instar *Aldoxⁿ* larva and in 91% of late second instar *bw* larva. Possible mechanisms of pseudotumor formation by JH are discussed.

- 6119 ADENYLATE CYCLASE ACTIVITY IN ADRENOCORTICOTROPIC HORMONE-SENSITIVE AND MUTANT ADRENOCORTICAL TUMOR CELL LINES. (E.) Schimmer, B. P. (Banting Best Dept. Med. Res., U. Toronto, Canada). *J Biol Chem* 247(10):3134-3138, 1972.

Adrenocorticotrophic hormone (ACTH) was added to cultures of three populations of adrenal tumors: Y-1 cells, which respond to ACTH with increased steroidogenesis, and two mutant cell lines, Y-6 and OS3, which are insensitive to ACTH. Adenylate cyclase activity in the three lines treated with ACTH was measured by observing the conversion of $(8\text{-}^{14}\text{C})\text{ATP}$ or $(2\text{-}^3\text{H})\text{ATP}$ to adenosine $3',5'$ -monophosphate (cAMP). Adenylate cyclase activity is stimulated by ACTH in Y-1 cells and Y-1 cell homogenates but not in Y-6 or OS3 cells. Homogenates of all three cell lines were stimulated by sodium fluoride. These observations demonstrate that Y-6 and OS3 cells are defective in the ability to accumulate cAMP in response to added ACTH and that this defect is the result of an adenylate cyclase which is insensitive to ACTH. Adenylate cyclase activity in Y-1, Y-6 and OS3 cells is not distinguishable in terms of requirements for fluoride ion, pH optima, stability at 37 C, optimum ATP:Mg^{2+} ratio and apparent K_m values. The findings that ATP, at concentrations in excess of Mg^{2+} , inhibit fluoride-stimulated adenylate cyclase in the three cell types, and that the inhibition is overcome by increased Mg^{2+} concentration, suggest that $\text{ATP}\cdot\text{Mg}$ is the substrate for adenylate cyclase.

- 6120 MOUSE-MYELOMA RNA POLYMERASE B. TEMPLATE-SPECIFICITIES AND THE ROLE OF A TRANSCRIPTION-STIMULATING FACTOR. (E.) Lentfer, D. (Max-Planck Inst. Exp. Med., Göttingen, West Germany) and A. G. Lezius. *Eur J Biochem* 30(2):278-284, 1972.

A DNA-dependent RNA polymerase was purified from homogenates of the mouse myeloma tumor, MOPC 70 E. A stimulating factor (heat-labile protein of 20,000-30,000 mol wt that restores double strand specificity) was also purified from the same system. The purified enzyme showed an absolute requirement for DNA, required Mn^{++} and medium ionic strength for maximum activity, and was totally inhibited by α -amanitin and phosphate ion, thus establishing it as RNA polymerase B. The template specificities were studied using native and heat-denatured DNA as well as synthetic double and single-stranded polydeoxynucleotides. Alternating polydeoxynucleotides (e.g., poly-[d(A-T-d(A-T))] and poly[d(I-C-d(I-C))] were the most efficient templates. The latter stimulated the incorporation of 3H -UTP into RNA by two orders of magnitude in the absence of stimulating factor when compared with the template activity of native DNA. The addition of factor resulted in only a two-fold increase in 3H -UTP incorporation with the alternating polydeoxynucleotide templates. Templates with a base composition similar to calf thymus DNA (e.g. poly[d(A-C-d(T-G))] and poly[d(A-G-d(T-C))] were intermediate in activity; however with these templates, factor stimulated 3H -UTP incorporation by five-fold. The homoduplexes (poly-(dA)·poly(dT), poly(dG)·poly(dC), and poly(dI)·poly(dC) were very poor templates both in the presence and absence of stimulating factor. Among the single-stranded templates assayed, poly(dI) and poly[d(T-G)] were completely inactive, whereas poly(dC) and poly(dT) were readily transcribed. The stimulating factor was probably not involved in transcription initiation since the rate of incorporation of γ - ^{32}P -ATP into RNA was unaltered in its presence.

- 6121 PHOSPHORYLASE AND GLYCOGEN IN THE SQUAMOUS CELL CARCINOMA OF THE LUNG AND BENIGN GROWTHS OF THE SQUAMOUS EPITHELIUM OF THE BRONCHI. (Rus.) Badmaeva, V. V. (P. A. Gertsen Moscow Res. Inst. Oncol., USSR). *Arkh Patol* 33(12):58-62, 1971.

The metabolism of glycogen and phosphorylase was studied histochemically in 20 lung cancer tumors, two bronchial papillomas and three cases of metaplastic bronchial mucosa. High phosphorylase activity was observed in the metaplastic bronchial epithelium and the squamous epithelium of the papillomas without signs of cell anaplasia. Phosphorylase activity in benign growths of the squamous epithelium in the lung was seen in areas of glycogen accumulation in mature epithelial cells. Differentiated forms of squamous cell carcinoma were characterized by loss of phosphorylase and the presence of free glycogen in tumor cells. Nondifferentiated squamous cell cancer differed from the more mature forms in the complete absence of glycogen and phosphorylase detected histochemically.

- 6122 GLUCURONIC ACID IN THE BLOOD AND URINE OF PATIENTS WITH CANCER AND PRECANCER OF THE MAMMARY GLAND. (Rus.) Al'pert, A. E. (Saratov Med. Inst., USSR) and A. M. Lunts. *Vopr Onkol* 17(11):28-31, 1971.

Blood and urine glucuronic acid levels were determined by the Marrog and Dische methods, resp., in 65 women (29-77 yr old) with mammary gland cancer and 15 women with precancerous fibrocystic mastopathy. The average level of blood glucuronic acid was similar in mammary cancer patients (7.2 mg%) and 54 healthy controls (6.9 mg%). Protein-containing serum fractions in which glucuronic acid may be combined with estrogens were less than 2.0 mg% in 3% of healthy subjects compared with 25% of cancer patients. Seventy-seven percent of healthy women but only 34% of tumor patients had total glucuronic acid levels between 5.0-8.9 mg%. Two groups of cancer patients were distinguished: those with very low (20%) and those with very high (22%) content of total glucuronic acid in blood. Analogous results were obtained in patients with precancerous conditions of the mammary gland, indicating early disturbances in glucuronic acid metabolism in the malignant process. There was a direct correlation between the stage of cancer and the total content of glucuronic acid in blood: the number of patients with hypoglucuronemia increased with the advance of cancer. It is suggested that blood glucuronic acid level and glucuronidase activity are related to the metabolism of estrogen and other steroid hormones.

- 6123 CHROMOSOME ABNORMALITIES IN AKR/TIALD LEUKAEMIAS. (E.) Legrand, E. (Curie Fdn., Paris, France) and J. F. Duplan. *Eur J Cancer* 7(6):485-490, 1971.

Chromosomal abnormalities of leukemic cells of X-irradiated AKR/TIALD mice were investigated. Mice 60-70 days old were exposed to 900 rads whole body radiation, while mice 30-37 days old received four weekly exposures of 175 rads each. All mice exposed to 900 rads were restored with AKR or TIALD bone marrow cells. Mice receiving four weekly irradiations were divided into three groups: mice restored with AKR bone marrow cells; mice restored with TIALD bone marrow cells; and mice remaining unrestored. All leukemias occurring in 900 rads irradiated mice developed from unirradiated donor cells, but in fractionally irradiated animals thymic lymphosarcomas developed from both host and donor thymic cells. Test animals showing obvious leukemia symptoms were sacrificed and cells from the thymus and marrow of the femur were prepared for chromosome study. Karyotype of cells showed the most frequent chromosome abnormality was a trisomy of the metacentric, probably originating from a nondisjunction. Since this trisomy has never been found in normal mice, it is considered a characteristic of leukemic cells.

- 6124 NONHISTONE CHROMOSOMAL PROTEINS IN SYNCHRONIZED HeLa CELLS. (E.) Bhorjee, J. S. (Worcester Fdn. Exp. Biol., Shrewsbury, Mass.)

and T. Pederson. *Proc Nat Acad Sci USA* 69(11): 3345-3349, 1972.

Synchronized HeLa cells in culture were fractionated and chromatin was isolated from their nuclei at different points in the cell cycle. Chromatin was separated into DNA, histones and nonhistone proteins. Nonhistone proteins, subjected to polyacrylamide gel electrophoresis, produced 22 distinct bands, corresponding to molecular wts of 5,000-180,000 daltons. Eighty-five percent of the material had molecular wts exceeding 40,000. The amounts of some nonhistone proteins remained the same at different stages in the cell cycle, while others changed by as much as 50%. Band 11, for instance, (75,000 molecular wt) decreased markedly in the early S phase, recovering in mid-S. Band 11 was reduced by 50% in mid-S and G₂.

6125 THE INFLUENCE OF PROTEOLYTIC ENZYMES INHIBITOR ON THE COURSE OF LYMPHOCYTE TRANSFORMATION *IN VITRO*. (E.) Tchorzewski, H. Dept. Gen. Exp. Path., Lodz, Poland) and A. Denys. *Experientia* 28(4):462-463, 1972.

It had previously been shown that the content of acid hydrolases in stimulated lymphocytes was increased. To study the possible role of proteolytic enzymes in stimulation, the effects of a proteolytic enzyme inhibitor were determined on *in vitro* PHA- and antigen-stimulated spleen and lymph node lymphocytes cultured from guinea-pigs preimmunized with human serum albumin. The protease inhibitor (200 µg/ml) significantly decreased (7- to 16-fold) the transformation rate of both spleen and lymph node lymphocytes *in vitro*, either after PHA or antigen stimulation, and slightly lowered ¹⁴C-leucine incorporation into cellular protein. The inhibitor had no significant effect on cell survival and did not affect oxygen consumption of transformed lymphocytes. It was concluded that the protease inhibitor prevented *in vitro* lymphocyte transformation by inhibiting protein synthesis.

6126 A FACTOR RESPONSIBLE FOR THE METABOLIC DEVIATIONS IN LIVER OF TUMOR-BEARING ANIMALS. (E.) Tanaka, T. (Inst. Protein Res., Osaka U., Japan), S. Yanagi, M. Miyahara, R. Kaku, H. Imamura, K. Taniuchi and M. Suda. *Gann* 63(5): 555-562, 1972.

The increase in type M₂ pyruvate kinase and in low K_m hexokinase activity was observed in the liver of 129 strains of mice following the i.p. transplantation of Ehrlich ascites tumor cells. Although there were great differences in enzyme activities among the different strains, both M₂ pyruvate kinase and low K_m hexokinase activities were consistently elevated in liver cell homogenates from tumor-bearing mice. The relative increases in the activities of both enzymes were greatest in those strains which showed lower activities in the control animals (e.g., 129, ICR and CF1 mice). The factor responsible for the stimulation in enzyme activity

could be recovered in the supernatant fraction of centrifuged ascites tumor cell sonicates (6,000 g for 15-25 min). The factor was heat stable but could not be acetone extracted. Intraperitoneal injection of bovine serum albumin into nontumor-bearing mice did not cause an increase in M₂ pyruvate kinase or low K_m hexokinase activity. The stimulating activity was present in an ultrafiltrate prepared from tumor cell sonicates, indicating that its molecular wt was less than 50,000.

6127 MECHANISM OF RESISTANCE TO STEROIDS: GLUCOCORTICOID RECEPTOR DEFECT IN LYMPHOMA CELLS. (E.) Rosenau, W. (Dept. Biochem., U. California, San Francisco), J. D. Baxter, G. G. Rousseau and G. M. Tomkins. *Nature New Biol* 237(70):20-24, 1972.

Mouse lymphoma cells, sensitive or resistant to the cytolytic effect of glucocorticoids, were treated with dexamethasone. Dexamethasone in concentrations of 2 x 10⁻⁸ M caused 99% cell lysis of sensitive lymphoma cells, while no cytolysis occurred in resistant cells, even at concentrations of 10⁻⁵ M. Cytosol of sensitive cells contained specific receptors which became saturated with dexamethasone at concentrations above 8 x 10⁻⁸ M; the capacity of cytosol from resistant cells to bind dexamethasone was 10% of the capacity of sensitive cells. Progesterone and 17α-hydroxyprogesterone decreased the lytic response of cells to dexamethasone and inhibited the binding of dexamethasone to cell cytosol. However, progesterone inhibited lysis and cytosol binding more effectively than 17α-hydroxyprogesterone. 17α-Methyltestosterone and testosterone did not cause lysis by themselves, but inhibited lysis by dexamethasone. Androstenedione inhibited neither the dexamethasone lytic effect nor the cytosol binding effect.

6128 SIMILARITIES OF THE ERYTHROCYTES IN JUVENILE CHRONIC MYELOGENOUS LEUKEMIA TO FETAL ERYTHROCYTES. (E.) Maurer, H. S. (Lincoln Sch. Med., U. Illinois, Chicago), L. N. Vida and G. R. Honig. *Blood* 39(6):778-784, 1972.

Erythrocytes from a four yr old boy with fatal juvenile chronic myelogenous leukemia were observed. The patient showed an enlarged spleen, myeloid hyperplasia, thrombocytopenia and low leukocyte alkaline phosphatase. The patient's blood cells had no Philadelphia chromosome. The erythrocytes had many features of erythrocytes of newborns. Fetal hemoglobin comprised 70-73% of the patient's blood hemoglobin, and the oxygen dissociation curve of whole blood was displaced to the left of that of normal adult blood. In addition, hemoglobin A₂ and the erythrocyte I antigen titer were reduced. The glycine:alanine ratio of the 136 position of the γ chain of the patient's fetal hemoglobin was similar to that seen in hemoglobin from newborns. These findings indicate that juvenile chronic myelogenous leukemia is accompanied by a reversion to fetal-type erythropoiesis.

- 6129 THE LIFE SPAN OF CELLULAR CULTURES FROM LEUKEMIC HUMAN BLOOD. (Fr.) Belpomme, D. (Hosp. Paul Brousse, Villejuif, France), P. Blondel and D. Grandjon. *C R Acad Sci [D](Paris)* 274(25):3480-3483, 1972.

The kinetic and morphological analysis of the cultures of 82 samples of human leukemic blood is presented. Blood samples of 20 cm³ were taken from patients with acute or chronic leukemias, either during the first perceptible stage or during a recurrent attack. Death of cultures was determined by nonacidification of the culture medium; absence of viable cells; and complete disappearance of cells from the monolayer adhering to the flasks. The establishment of a permanent line of cultures was determined by their growth curve. Of the 82 samples, 10 could be used to establish 16 permanent lymphoblastoid lines in 12-122 days. Of these, seven derived from acute lymphoid leukemia (LAL), two from acute myelogenous leukemia (LAM), and one from chronic myelogenous leukemia (LMC) bloods; it was not possible to obtain a line from chronic lymphoid leukemia (LLC) blood. The remaining 72 samples produced cultures of a limited life span, the peaks on a distribution curve showing life spans on days 26, 59, and 85. Specimens showing at least one viable culture at different times following culture initiation were divided into four groups based on survival time: 28 specimens with a life span of 10-33 days; 28 with a life span of 35-65 days; 16 with a survival of 66-122 days; and 10 with permanent lines. Of these groups, the second was associated with large monocytoid cells, the third with small monocytoid or microcells, and the fourth with lymphoblasts.

- 6130 RETINOBLASTOMA AND D-CHROMOSOME DELETIONS (E.) Orye, E. (Pediatric Clin., St. U. Ghent, Belgium), M. J. Delbeke and B. Vandenabeele. *Lancet* 2:1376, 1971.

Additional evidence is given consistent with the hypothesis that a locus on the long arm of a D chromosome is concerned in the development of retinoblastoma. All mitoses of PHA-stimulated lymphocytes and directly processed bone-marrow cells from a patient with retinoblastoma had a deletion of the long arm of a D chromosome. The chromosome was identified as number 13 by autoradiography, quinacrine fluorescence, and analysis of the DNA d-r Giemsa banding pattern. The missing section was the broadest of the three bands normally present in that arm. The chromosomes of the parents were normal. The patient had no mental retardation, and only congenital anomalies were bilateral clinodactyly and cleft uvula.

(5):50-54, 1972.

189 A CLINICO-STATISTICAL ANALYSIS OF OPERABLE
AND INOPERABLE PATIENTS WITH GASTRIC CANCER.
(Rus.) Shkrob, O. S. (N. N. Burdenko Fac. Surg. Clin.
SR Acad Sci., Moscow), D. B. Korman, N. M. Isaev
and A. I. Agureev. *Vopr Onkol* (8):16-21, 1972.

190 IN VITRO GROWTH FEATURES OF VARIOUS MYXOMA-
TOUS HUMAN NEOPLASMS. (Rus.) Shcherbakova,
G. (N. N. Petrov Res. Inst. Oncol. USSR Ministry
Public Hlth., Leningrad) and Ju. G. Puchkov. *Vopr
Onkol* (8):43-50, 1972.

191 PRIMITIVE CARCINOMA OF OPERATED STOMACH.
(CLINICAL CONTRIBUTION.) (It.) Nigro, R.
Inst. Surg. Semeiol., U. Naples, Italy) and M.
Gönnauer. *Rass Int Clin Ter* 52(8):458-469, 1972.

192 CYTOMORPHOLOGICAL AND IN VITRO GROWTH

CHARACTERISTICS OF TUMOR CELLS FROM OVARIAN
CANCER EXUDATES. (Rus.) Lipova, V. A. (N. N. Petrov
Res. Inst. Oncol. USSR Ministry Public Hlth., Lenin-
grad). *Vopr Onkol* (8):35-43, 1972.

6193 UNUSUAL TUBULES IN THE ENDOPLASMIC RETICULUM
OF THYROID TUMOUR CELLS. (Ger.) Deutsch-
länder, N. (Veterinary Fac., U. Munich, Germany).
Virchows Arch (Zellpathol) 11:11-18, 1972.

6194 LACRIMAL GLAND ADENOID CYSTIC CARCINOMA.
WITH REFERENCE TO ONE CASE. (Sp.) Jofre,
J. A. (Med. Sci. Dept., Natl. Cuyo U., Mendoza,
Argentina) and G. O. Otero. *Rev Med Mex*
52(1133):255-260, 1972.

6195 ADENOCARCINOMA OF THE BREAST IN WOMEN LESS
THAN 30 YEARS-OF-AGE. (Fr.) Rouesse, J.
(Gustave-Roussy Inst., Villejuif, France), G. Contesso,
J. Genin, D. Sarrazin, J. Weiler and F. May-Levin.
Bull Cancer 59(1):41-60, 1972.

6196 ALDOLASE ISOZYMES IN LUNG CANCER TISSUES.
(Jap.) Nakamoto, Y. (Tokyo Med. Coll.,
Japan). *J Tokyo Med Coll* 30(1):1-18, 1972.

6197 CHROMOSOME ANALYSIS OF A PRIMARY CARCINOMA
OF THE FALLOPIAN TUBE. (E.) Weise, W.
(Med. Acad., Magdeburg, Germany) and H. H. Büttner.
Humangenetik 15(2):196-197, 1972.

6198 PRIMARY GASTROINTESTINAL LYMPHOMA - A CLIN-
ICAL STUDY OF FIFTY-SEVEN CASES. (E.)
Kahn, L. B. (U. Cape Town Med. Sch., South Africa),
G. Selzer and R. O. C. Kaschula. *Digest Dis*
17(3):219-232, 1972.

- 6281 ULTRASTRUCTURAL STUDY OF LIVER INVASION BY NOVIKOFF HEPATOMA. (E.) Babai, F. (Fac. Med., U. Montreal, Canada) and G. Tremblay. *Cancer Res* 32(12):2765-2770, 1972.
- 6282 REGULATION OF THE EMBDEN-MEYERHOF PATHWAY IN A TRANSPLANTABLE RAT THYROID TUMOR. (E.) Meldolesi, M. F. (Inst. Gen. Path., U. Naples, Italy) and V. Macchia. *Cancer Res* 32(12):2793-2798, 1972.
- 6283 CHRONIC MUCOCUTANEOUS CANDIDIASIS, MYOSITIS, AND THYMOMA. A NEW TRIAD. (E.) Montes, L. F. (U. Alabama, Birmingham Med. Ctr.), R. Ceballos, M. D. Cooper, M. N. Bradley and D. E. Bockman. *J Am Med Assoc* 222(13):1619-1623, 1972.
- 6284 PREPARATION AND CHARACTERIZATION OF 80S RIBOSOMES OF ASCITES TUMOR CELLS ACTIVE IN POLYPEPTIDE SYNTHESIS. (E.) Letnansky, K. (Inst. Cancer Res., U. Vienna, Austria). *Cancer Res* 32(12):2633-2642, 1972.
- 6285 EXPERIMENTAL STUDY OF THE METASTATIC SPREAD OF TUMOR CELLS IN EMBRYONATED CHICKEN EGG. DISTRIBUTION, HISTOLOGY AND ULTRASTRUCTURAL ASPECTS OF TUMOROUS FOCUSES. (Fr.) Vlaeminck, M. N. (Inst. Cancer Res., Lille, France), L. Adenis, Y. Mouton and A. Demaille. *Int J Cancer* 10(3):619-631, 1972.
- 6286 THE PRESENCE OF A POLYRIBOADENYLIC ACID-

DEPENDENT DNA POLYMERASE IN EUKARYOTIC CELLS. (E.) Bolden, A. (Roche Inst. Molecular Biol., Nutley, N.J.), M. Fry, R. Muller, R. Citarella and A. Weissbach. *Arch Biochem Biophys* 153(1):26-33, 1972.

6287 COMPARATIVE STUDY OF LYSOZYMES FROM LEUCOCYTES OF NORMAL PERSONS AND OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA. (Fr.) Perin, J.-P. (Biochem. Lab., U. Paris, France) and P. Jolles. *Clin Chim Acta* 42(1):77-84, 1972.

6288 STUDIES ON DNA SYNTHESIS IN MURINE MYELOMA: II. ACTIVATION OF LATENT RNA-DEPENDENT DNA POLYMERASE ACTIVITY IN MEMBRANE FRACTIONS. (E.) Wilson, S. H. (Natl. Cancer Inst., Bethesda, Md.), E. L. Kuff, E. W. Bohn and K. K. Leuders. *Biochem Biophys Res Commun* 49(4):1093-1099, 1972.

6289 NUCLEAR DNA-DEPENDENT RNA POLYMERASES OF EHRlich ASCITES TUMOR CELLS: TWO DISCRETE α -AMANITIN-SENSITIVE FORMS. (E.) Blair, D. G. R. (Dept. Cancer Res., U. Saskatchewan, Saskatoon, Canada) and M. Dommasch. *Biochem Biophys Res Commun* 49(4):877-883, 1972.

6290 ACTIVITIES AND QUANTITIES OF LYSOSOMAL ENZYMES DURING MAMMARY TUMOR REGRESSION. (E.) Lanzerotti, R. H. (Natl. Cancer Inst., Bethesda, Md.) and P. M. Gullino. *Cancer Res* 32(12):2679-2685, 1972.

6291 ULTRAMORPHOLOGICAL AND ULTRACYTOCHEMICAL STUDIES ON TUBULORETICULAR STRUCTURES IN LYMPHOID CELLS. (E.) Schaff, Z. (Natl. Cancer Inst., Bethesda, Md.), U. Heine and A. J. Dalton. *Cancer Res* 32(12):2696-2706, 1972.

6292 ELECTROPHORETIC ANALYSIS OF MICROSOMAL SMOOTH MEMBRANE PROTEINS IN RAT LIVER AND IN MORRIS HEPATOMA 5123C. (E.) Chiarugi, V. P. (Inst. Gen. Path., U. Florence, Italy). *Cancer Res* 32(12):2707-2710, 1972.

6293 THE INDUCTION OF ORNITHINE DECARBOXYLASE IN CULTURED HEPATOMA CELLS. (E.) Hogan, B. (Sch. Biol. Sci., U. Sussex, Falmer, Brighton, England) and A. Blackledge. *Biochem J* 130(2):78-79, 1972.

6294 THE INDUCTION OF ORNITHINE DECARBOXYLASE DURING LYMPHOCYTE STIMULATION BY PHYTOHAEMAGGLUTININ. (E.) Kay, J. E. (Sch. Biol. Sci., U. Sussex, Falmer, Brighton, England) and V. J. Lindsay. *Biochem J* 130(2):78, 1972.

6295 IS AGING OF TUMOR CELLS RELATED TO THE ALTERATION OF STEMLINE KARYOTYPES? (E.) Yosida, T. H. (Natl. Inst. Genetics, Misima, Japan).

Proc Jap Acad 48(4):268-273, 1972.

6296 DISTANT CUTANEOUS METASTASES IN A PATIENT WITH SQUAMOUS-CELL CARCINOMA OF THE LIP. (E.) Bordin, G. M. (VA Hosp., Albuquerque, N.M.) and S. Weitzner. *Oral Surg* 34(3):445-449, 1972.

6297 FIBROSARCOMA (MALIGNANT FIBROXANTHOMA) INVOLVING CONJUNCTIVA AND CILIARY BODY. (E.) Delgado-Partida, P. (Med. Ctr. La Raza Mexican Inst. Social Security, Mexico City) and F. Rodriguez-Trujillo. *Am J Ophthalmol* 74(3):479-485, 1972.

6298 ENDOMETRIAL CARCINOMA: AN ANALYSIS OF 355 CASES TREATED AT ST. THOMAS' HOSPITAL, 1945-69. (E.) Milton, P. J. D. (No affiliation) and J. S. Metters. *J Obstet Gynecol Br Commonw* 79(5):455-464, 1972.

6299 ABNORMALITIES OF PLATELET FUNCTION IN THE MYELOPROLIFERATIVE DISORDERS. (E.) Cardamone, J. M. (Hennepin Cty. Gen. Hosp., Minneapolis, Minn.), J. R. Edson, J. R. McArthur and H. S. Jacob. *J Am Med Assoc* 221(3):270-273, 1972.

6300 LANTHANUM-INDUCED ALTERATIONS OF CELLULAR ELECTROLYTES IN EHRlich ASCITES TUMOR CELLS: A NEW VIEW. (E.) Levinson, C. (U. Texas Med. Sch., San Antonio), T. C. Smith and T. M. Miki-ten. *J Cell Physiol* 80(1):149-154, 1972.

6301 LEUCOCYTE FUNCTION IN DOWN'S SYNDROME AND ACUTE LEUKAEMIA. (E.) Gregory, L. (Welsh Natl. Sch. Med., Cardiff), E. Thompson and R. Williams. *Lancet* (7765):1359-1361, 1972.

6302 CARCINOMA OF THE MALE BREAST IN ZAMBIA. (E.) Bhagwande, S. B. (Dept. Path., U. Zambia, Lusaka). *East Afr Med J* 49(2):89-93, 1972.

6303 EFFECT OF ADENOSINE 3'-5'-CYCLIC MONOPHOSPHATE ON CELL PROLIFERATION. (E.) Froehlich, J. E. (Northwestern U., Sch. Med., Chicago, Ill.) and M. Rachmeler. *J Cell Biol* 55(1):19-31, 1972.

6304 INVESTIGATION OF THE THROMBOPLASTIC ACTIVITY OF EOSINOPHILS IN A PATIENT WITH EOSINOPHILIC LEUKEMIA. (Fr.) Malkiewicz, B. (Med. Acad., Cracow, Poland), W. Pajdak, J. Okulski and J. Lisiewicz. *Haematologia* 5(4):439-446, 1971.

6305 ULTRASTRUCTURE OF A BRONCHIAL CARCINOID. (Rus.) Oppermann, A. (Path. Anat. Hosp. Ctr. Besancon, France), J. Carbile and G. Pageaut. *Ark Patol* 34(3):32-39, 1972.

- 306 COLONIC LYMPHOMA IN ULCERATIVE COLITIS: REPORT OF FOUR CASES. (E.) Nugent, W. (New England Deaconess Hosp., Boston, Mass.), Zuberi, M. B. Bulan and M. A. Legg. *Lahey Clin Found Bull* 21(3):104-111, 1972.
- 307 CULTURAL CHARACTERISTICS OF A CELL LINE DERIVED FROM AN EQUINE SARCOID. (E.) Watson, R. E., Jr. (Dept. Microbiol., Colorado St. Univ., Fort Collins), J. J. England and K. A. Larson. *Appl Microbiol* 24(5):727-731, 1972.
- 308 INTERFERON INDUCTION IN NORMAL AND LEUKEMIC HUMAN LYMPHOCYTE CULTURES BY FLUOROURACIL HYDROCHLORIDE. (E.) Dennis, A. J. (Coll. Biol. Sci., Ohio St. U., Columbus), H. E. Wilson, D. Barker and M. S. Rheins. *Proc Soc Exp Biol Med* 141(3):782-785, 1972.
- 309 CHORIOCARCINOMA *IN VITRO*: EVIDENCE FOR EXCHANGE OF ENZYMES BETWEEN CULTURE MEDIUM AND CELLS. (E.) Edlow, J. B. (Natl. Inst. Health, Bethesda, Md.), P. O. Kohler and J. C. Robinson. *Proc Soc Exp Biol Med* 141(3):798-801, 1972.
- 310 ASPIRIN AND TUMOUR METASTASIS. (E.) Wood, S., Jr. (Merck Inst. Therap. Res., Rahway, N.J.) and P. Hilgard. *Lancet* 11(7792):1416-1417, 1972.
- 311 TO THE PROBLEM OF THE LIP CANCER METASTASES. (E.) Durkovsky, J. (Oncological Inst. Slovakia, Bratislava, Czechoslovakia), M. Krajci and B. Michalikova. *Neoplasma* 19(6):653-659, 1972.
- 312 PARTIAL PURIFICATION OF A TUMOR tRNA-GUANINE METHYLTRANSFERASE. (E.) Chan, C.-C. (Dept. Biochem., McGill U., Montreal, Canada) and M. J. Fraser. *Life Sci* 11(16):793-805, 1972.
- 313 THE "LOST" PATIENT: A DISCUSSION OF CARCINOMA OF THE CECUM -- ASCENDENS. (E.) McAdams, A. J. (Western Pennsylvania Hosp., Pittsburgh). *South Med J* 65(7):872-884, 1972.
- 314 PULMONARY LYMPHOMA VERSUS PSEUDOLYMPHOMA: A PERPLEXING PROBLEM. (E.) Greenberg, J. D. (Baylor Coll. Med., Houston, Tex.), J. G. Reisler, F. Gyorkey and D. E. Jenkins. *South Med J* 65(7):775-784, 1972.
- 315 PRIMARY SQUAMOUS-CELL CARCINOMA ARISING IN A SOLITARY NON-PARASITIC CYST OF THE LIVER. (E.) Greenwood, N. (Dept. Path., Surg., Manchester, England) and W. McN. Orr. *J Pathol* 107(2):145-148, 1972.
- 316 A HISTOCHEMICAL STUDY OF MUCINS IN NORMAL AND NEOPLASTIC HUMAN PANCREATIC TISSUE. (E.) Roberts, P. F. (Radcliffe Infirm., Oxford, England) and J. Burns. *J Pathol* 107(2):87-94, 1972.
- 6317 LYMPHOSARCOMA OF JAWS RESEMBLING BURKITT'S TUMOR. (E.) Takagi, M. (Tokyo Med. Dental U., Japan) and G. Ishikawa. *Acta Pathol Jap* 22(2):391-407, 1972.
- 6318 LEUKEMIA IN SOUTHERN IRAN. (E.) Mohalla-tee, E. A. (Nemazee Hosp., Shiraz, Iran). *Indian J Med Sci* 26(5):313-314, 1972.
- 6319 CONTROL OF CELL PROLIFERATION IN MAMMALIAN CELLS: ROLE OF NUCLEAR ACIDIC PROTEINS. (E.) Baserga, R. (Temple U. Sch. Med., Philadelphia, Pa.). *J Invest Dermatol* 59(1):21-23, 1972.
- 6320 ADENOCARCINOMA OF THE RETE TESTIS. (E.) Whitehead, E. D. (New York U. Med. Ctr., N.Y.), Q. J. Valensi and J. S. Brown. *J Urol* 107:992-999, 1972.
- 6321 TUMOR-INDUCED HYPERCALCEMIA. (E.) Rudd, F. V. (Dept. Urology, Med., U. Washington, Seattle), R. K. Root, R. W. Skoglund, Jr. and J. S. Ansell. *J Urol* 107:986-989, 1972.
- 6322 ULTRASTRUCTURAL STUDY OF CYTOCHROME OXIDASE IN ONCOCYTOMA. (E.) Kobayashi, H. (Aichi Cancer Ctr. Hosp., Japan), M. Hosino and H. Tauchi. *Naoya J Med Sci* 34(1):25-32, 1972.
- 6323 OXYGEN TENSION IN HUMAN MALIGNANT TUMORS. (E.) Kuroda, Y. (Jikei U. Sch. Med., Japan), K. Nyunoya and M. Gomi. *Jikei Med J* 18(3/4):157-168, 1971.
- 6324 ELECTRON MICROSCOPY IN *IN SITU* AND INVASIVE VULVAR PAGET'S DISEASE. (E.) Nielson, D. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and J. D. Woodruff. *Am J Obstet Gynecol* 113(6):719-732, 1972.
- 6325 INTRAEPITHELIAL CARCINOMA OF THE VULVA. (E.) Boutsellis, J. G. (Dept. Obstetrics Gynecol., Ohio State U., Columbus). *Am J Obstet Gynecol* 113(6):733-738, 1972.
- 6326 PRIMARY MALIGNANT MELANOMA OF THE SKIN METASTATIC TO THE EYE. (E.) Ferry, A. P. (Mount Sinai Sch. Med., City U. New York, N.Y.). *Am J Ophthalmol* 74(1):12-19, 1972.
- 6327 ORBITAL TUMOURS IN IRAQ. (E.) Talib, H. (Med. Ctr. Teaching Hosp., U. Baghdad,

- Iraq). *Ann R Coll Surg Engl* 51(1):31-40, 1972.
- 6328 THE BIOLOGY OF BLADDER CANCER. (E.)
Cooper, E. H. (U. Leeds, England).
Ann R Coll Surg Engl 51(1):1-16, 1972.
- 6329 PRODUCTION OF HUMAN NERVE-GROWTH FACTOR
IN A PATIENT WITH A LIPOSARCOMA. (E.)
Waddell, W. R. (U. Colorado Sch. Med., Denver),
M. N. Goldstein, R. A. Bradshaw and W. M. Kirsch.
Lancet (7765):1365-1367, 1972.
- 6330 HIGH-VOLTAGE ELECTRON MICROSCOPY OF WET
WHOLE CANCER AND NORMAL CELLS. VISUAL-
IZATION OF CYTOPLASMIC STRUCTURES AND SURFACE PRO-
JECTIONS. (E.) Parsons, D. F. (Roswell Park Mem.
Inst., Buffalo, N.Y.), V. R. Matricardi, J. Subjeck,
I. Uydess and G. Wray. *Biochim Biophys Acta*
290:110-124, 1972.
- 6331 ELEVATION OF PEPTIDYLPROLINE HYDROXYLASE
ACTIVITY AND COLLAGEN SYNTHESIS IN
SPONTANEOUS PRIMARY MAMMARY CANCERS OF INBRED MICE.
(E.) Cutroneo, K. R. (Med. Coll. Georgia, Augusta),
N. A. Guzman and A. G. Liebelt. *Cancer Res* 32(12):
2828-2833, 1972.
- 6332 ULTRASTRUCTURAL CYTOCHEMICAL DEMONSTRATION
OF TARTRATE-RESISTANT ACID PHOSPHATASE
ISOENZYME ACTIVITY IN "HAIRY CELLS" OF LEUKEMIC
RETICULOENDOTHELIOSIS. (E.) Katayama, I. (Boston
U. Sch. Med., Mass.), C. Y. Li and L. T. Yam.
Am J Path 69(3):471-482, 1972.
- 6333 ISOLATION OF mRNA FROM KB-CELLS BY
AFFINITY CHROMATOGRAPHY ON POLYURIDYLIC
ACID COVALENTLY LINKED TO SEPHAROSE. (E.) Lindberg,
U. (Microbiol. Inst., Uppsala U., Sweden) and T.
Persson. *Eur J Biochem* 31(2):246-254, 1972.
- 6334 EFFECT OF ALBUMIN ON BILIRUBIN CONJUGATION
AND TOXICITY IN CELL CULTURE OF A CLONAL
STRAIN OF RAT HEPATOMA CELLS. (E.) Bratlid, D. (U.
Hosp., Rikshospitalet, Oslo, Norway) and H. E. Rugstad.
Scand J Lab Invest 29(4):461-465, 1972.
- 6335 THE ULTRASTRUCTURE OF TUMOURS DERIVED FROM
SPONTANEOUSLY TRANSFORMED TISSUE CULTURE
CELLS. (E.) Wilson, P. D. (Imperial Cancer Res.
Fund, London, England) and L. M. Franks. *Br J*
Cancer 26(5):380-388, 1972.
- 6336 PRODUCTION OF METASTASES BY A PRIMARY
TUMOUR IRRADIATED UNDER AEROBIC AND ANAE-
ROBIC CONDITIONS *IN VIVO*. (E.) Brenk, H. A. S. van
den (St. Thomas' Hosp., London, England), V. Moore,
C. Sharpington and C. Orton. *Br J Cancer* 26(5):
402-412, 1972.
- 6337 ABO BLOOD GROUPS, RHESUS FACTOR AND INTEST-
INAL METAPLASIA OF THE STOMACH. (E.) Glo-
ber, G. (Radcliffe Infirmary, Oxford, England), A. S.
Pena, R. Whitehead, M. W. L. Gear, M. Roca, G.
Kerrigan and S. C. Truelove. *Br J Cancer* 26(5):
420-422, 1972.
- 6338 PLATELET AND FIBRINOGEN KINETICS IN THE
CHRONIC MYELOPROLIFERATIVE DISORDERS. (E.)
Brodsky, I. (Hahnemann Med. Coll. Hosp., Philadel-
phia, Pa.), S. B. Kahn, E. M. Ross and G. Petkov.
Cancer 30(6):1444-1450, 1972.
- 6339 THE EFFECT OF THIOLS ON OESTRADIOL BIND-
ING BY COMPONENTS OF HUMAN MALIGNANT
BREAST TUMORS. (E.) Braunsberg, H. (Med. Res.
Council Clin. Endocrinology Unit, Edinburgh, Scot-
land), E. Killen and S. G. Richardson. *Biochem J*
130(1):38, 1972.
- 6340 POLAROGRAPHIC ANALYSIS OF SERUM AND
CEREBROSPINAL FLUID IN MENINGOENCEPHA-
LITIS AND BRAIN TUMORS. (E.) Moyseyenko, L. Ye.
(Inst. Inf. Dis. Kiev, USSR). *Zh Nevropatol*
Psikhiatr 72(6):854-857, 1972.
- 6341 ULTRAVIOLET INDUCIBLE FLUORESCENCE OF
TUMOUR CELLS SUPRAVITALLY STAINED WITH
THIAZINE DYES. (E.) Marques, D. (Francisco
Gentil Portuguese Inst. Oncol., Lisbon, Portugal) and
A. L. Bastos. *Exp Cell Res* 73(2):525-528, 1972.
- 6342 CARCINOMA OF THE BREAST IN WOMEN AGED
BETWEEN 35 AND 45 YEARS. (E.) Singer,
A. M. (St. Vincent's Hosp., Melbourne, Australia),
R. C. Bennett, H. Frydenberg, I. S. Russell and
D. P. S. Chan. *Med J Aust* (23):1200-1210, 1972.
- 6343 SEPARATION OF ASCITES MYELOMA CELLS,
LYMPHOCYTES AND MACROPHAGES BY ZONAL
CENTRIFUGATION ON AN ISOKINETIC GRADIENT. (E.)
Stewart, M. J. (Sch. Med., Dentistry, U. Alabama,
Birmingham), T. G. Pretlow II and R. Hiramoto. *Am J*
Pathol 68(1):163-182, 1972.
- 6344 INTERACTION OF POLYNUCLEOTIDES WITH
CULTURED MAMMALIAN CELLS. 1. UPTAKE OF
RNA BY EHRlich ASCITES CARCINOMA CELLS. (E.)
Juliano, R. (Roswell Park Mem. Inst., Buffalo,
N.Y.) and E. Mayhew. *Exp Cell Res* 73(1):3-12, 1972.
- 6345 PROPERTIES OF RNA POLYMERASE FROM A TRANS-
PLANTABLE BRAIN TUMOR. (E.) Menon, I. A.
(Med. Sci. Building, U. Toronto, Canada). *Brain Res*
42(2):529-533, 1972.
- 6346 NUCLEAR LOBULATION AND CYTOPLASMIC FIBRILS
IN LEUKEMIC PLASMA CELLS. (E.)

Beltran, G. (Tulane U. Sch. Med., New Orleans, Louisiana) and W. J. Stuckey. *Am J Clin Pathol* 58(2):159-164, 1972.

6347 ULTRASTRUCTURAL ALTERATIONS INDUCED BY AIR DRYING, WRIGHT'S AND PAS STAINING AND THEIR RELATIONSHIP TO MALIGNANCY ASSOCIATED CHANGES (MAC) IN LEUKOCYTES. (E.) Paegle, R. D. (St. Vincent's Hosp., Med. Ctr., New York, N.Y.). *Acta Cytol* 16(5):466-471, 1972.

6348 CYTOLOGY OF URINE FROM DOGS WITH BORTRYOID SARCOMA OF THE BLADDER. (E.) Roszel, J. F. (Oklahoma St. U., Coll. Vet. Med., Stillwater). *Acta Cytol* 16(5):443-446, 1972.

6349 EVIDENCE FOR AND PURIFICATION OF A RIFAMPICIN-INSENSITIVE, DNA-DEPENDENT RNA POLYMERASE FROM EHRlich-ASCITES TUMOR CELLS. (Ger.) Jackisch, R. (Physiological-Chem. Inst. U. Tübingen, West Germany), A. Jung, W. Schlegel and D. Mayer. *Loppe Seylers Z Physiol Chem* 353(11):1705-1715, 1972.

6350 ON THE DIAGNOSIS AND TREATMENT OF SKIN CANCER FROM ULCERS AND OSTEOMYELITIC FISTULAS. (Rus.) Petrov, V. I. (S. M. Kirov Military Acad. Med. Sci., Leningrad, USSR), M. V. Grinev and V. G. Petrov. *Vopr Onkol* 18(9):72-77, 1972.

6351 DNase ACTIVITY IN TUMOR GROWTH AND THE EFFECT OF EHRlich CARCINOMA ASCITIC FLUID RNA ON IT. (Rus.) Ryazantseva, I. N. (V. I. Ul'yanov-Lenin State U., Kazanj, USSR), M. I. Belyaeva and V. G. Vinter. *Vopr Onkol* 18(9):33-37, 1972.

6352 HISTOCHEMICAL PROPERTIES OF "C" CELLS AND SOLID THYROID CANCER WITH AMYLOIDOSIS OF THE STROMA. (Rus.) Mikhailov, I. G. (USSR Acad. Med. Sci., Moscow). *Vopr Onkol* 18(9):13-18, 1972.

6353 RECOGNITION OF A PERSISTANT CAVITARY FORM OF PULMONARY CANCER. (Rus.) Krol, Ya. M. (S. M. Military Acad. Med. Sci. Leningrad, USSR) and S. I. Popandopulo. *Vopr Onkol* 18(9):19-22, 1972.

6354 ANOMALIES OF THE SMALL ACROCENTRIC CHROMOSOMES IN HUMAN TUMOUR CELLS. (E.) Spiers, A. S. D. (Royal Postgrad. Med. Sch., London, England) and A. G. Baikie. *Aust NZ J Med* 2(2):188-202, 1972.

6355 THE RELATIONSHIP OF MENSTRUAL STATUS AND OTHER RISK FACTORS TO RECURRENCE OF CARCINOMA OF THE BREAST. (E.) Hyman, B. (Natl. Cancer Inst., Bethesda, Md.), M. H. Myers and D. Schottenfeld. *Am J Epidemiol* 96(3):173-182, 1972.

6356 FLUCTUATION OF LIPID CONTENT IN EHRlich CARCINOMA-BEARING MOUSE LIVER DURING THE GROWTH PERIOD. (E.) Kudo, T. (Res. Inst. Tuberculosis, Leprosy, Cancer, Tohoku U., Sendai, Japan). *Sci Rep Res Inst Tohoku Univ [Med]* 18(3-4):56-64, 1971.

6357 IMPLANTATION OF TUMOR CELLS IN SURGICAL WOUNDS. (Heb.) Zer, M. (Beilinson Hosp., Petah Tikva, Israel) and M. Dintsman. *Harefuah* 83(3):102, 1972.

6358 DIFFERENTIATION OF METASTASES OF MAMMARY CARCINOMA AND SURVIVAL. (Pol.) Smolak, K. (Oncological Inst., Cracow, Poland) and H. Kolodziejska. *Patol Pol* 23(3):309-316, 1972.

6359 CAVERNOUS HAEMANGIOMA WITH PLASMA CELL PROLIFERATION. (Ger.) Boros, B. (Med. U. Pecs, Hungary) and I. Agoston. *Acta Chir Acad Sci Hung* 12(4):315-324, 1971.

6360 FOUR PATIENTS DEVELOPING DONOR-CANCER AFTER KIDNEY GRAFTS. (Sp.) Lanari, A. (Fac. Med., U. Buenos Aires, Argentina), J. E. Rodo, J. A. Barcat, M. Molins, G. Gallo Morando, M. Torres Agüero and O. Lopez Blanco. *Medicine* 37(2):79-92, 1972.

6361 SERUM ENZYME PATTERN FOR LIVER METASTASES IN AH109A-BEARING RATS. (E.) Maezawa, S. (Res. Inst. Tuberculosis, Leprosy, Cancer, Tohoku U., Sendai, Japan). *Sci Rep Res Inst Tohoku Univ [Med]* 18(3-4):65-85, 1971.

6362 Y-CHROMATIN OF INTERPHASE CANCER CELLS, A PRELIMINARY STUDY. (E.) Litton, L. E. (Johns Hopkins U. Sch. Med., Baltimore, Md.), D. H. Hollander, D. S. Borgaonkar and J. K. Frost. *Acta Cytol* 16(5):404-407, 1972.

6363 LEIOMYOSARCOMA IN THE SKIN. A CASE REPORT. (E.) Chaves, E. (Fac. Med., U. Paraiba, Brazil), H. H. Sa, N. Gadelha and E. Vasconcelos. *Acta Derm Venereol* 52(4):288-290, 1972.

6364 LONGEVITY OF MALE AND FEMALE, INTACT AND GONAECTOMIZED, UNTREATED AND HORMONE-TREATED, NEOPLASTIC AND NON-NEOPLASTIC SYRIAN HAMSTER. (E.) Kirkman, H. (Stanford U. Sch. Med., Calif.) and P. K. S. Yau. *Am J Anat* 135(2):205-219, 1972.

6365 TUMOUR AND PLASMA ACTH CONCENTRATIONS IN PATIENTS WITH AND WITHOUT THE ECTOPIC ACTH SYNDROME. (E.) Ratcliffe, J. G. (St. Bartholomew's Hosp., London, England), R. A. Knight, G. M. Besser, J. Landon and A. G. Stansfeld. *Clin Endocrinol* 1(1):27-44, 1972.

- 6366 ACTH SECRETION BY BRONCHIAL CARCINOID TUMOURS. (E.) Mason, A. M. S. (Southampton Gen. Hosp., London, England), J. G. Ratcliffe, R. M. Buckle and A. S. Mason. *Clin Endocrinol* 1(1):3-25, 1972.
- 6367 THE FINE STRUCTURE OF NUCLEI AS REVEALED BY ELECTRON MICROSCOPY. VIII. INTRA-NUCLEAR CANALICULUS COMPLEX IN EHRlich ASCITES TUMOR CELLS AND ITS FUNCTIONAL SIGNIFICANCE. (E.) Sugihara, R. (Nara Med. U., Kashihara City, Japan) and G. Yasuzumi. *Okajimas Folia Anat Jap* 49(1):55-64, 1972.
- 6368 CLINICOPATHOLOGICAL AND ELECTRONMICROSCOPICAL STUDIES ON MELANOTIC FRECKLE HUTCHINSON AND MALIGNANT MELANOMA ARISING FROM THE MELANOTIC FRECKLE. (E.) Arao, T. (Dept. Dermatology, Kumamoto U. Med. Sch., Japan), H. Kuwahara and S. Inoue. *Jap J Dermatol* 81(4):444-453, 1971.
- 6369 SOME PROBLEMS IN EVALUATION THE MORPHOLOGY OF GYNAECOLOGICAL TUMOURS IN ORGAN CULTURES. (E.) Siracky, J. (Cancer Res. Inst. Slovak Acad. Sci., Bratislava, Czechoslovakia) and E. Siracka. *Neoplasma* 19(5):525-529, 1972.
- 6370 POLYNUCLEOTIDASES IN MOUSE ASCITIC TUMOUR CELLS. (E.) Horakova, K. (Fac. Chem. Technology, SVST, Bratislava, Czechoslovakia). *Neoplasma* 19(5):459-468, 1972.
- 6371 IDENTIFICATION OF MITOCHONDRIAL RIBOSOMES OF EHRlich ASCITES TUMOUR CELLS. (E.) Kuzela, S. (Cancer Res. Inst., Slovak Acad Sci., Bratislava, Czechoslovakia), V. Krempasky, E. Bohunicka and V. Ujhazy. *Neoplasma* 19(5):469-475, 1972.
- 6372 OBTAINING A CELL LINE, DERIVED FROM AN MOPC 173 MURINE PLASMOCYTOMA CULTIVATED IN A SERUM DEPRIVED MEDIUM. (Fr.) Guerin, C. (Molecular Biol. Inst., Paris, France) and M.-A. Moyne. *C R Acad Sci [D] (Paris)* 275(19):2157-2160, 1972.
- 6373 THE INTRACELLULAR LOCALIZATION OF CHOLINESTERASE IN TUMORS. (Rus.) Popkova, G. A. (M. M. Shemyakin Inst. Natural Compound Chemistry, USSR Akad. Sci., Moscow, USSR), N. P. Gor'kova, N. G. Timofeyeva, E. V. Dyatlovitskaya and L. D. Bergel'son. *Dokl Akad Nauk SSSR* 207(1):232-234, 1972.
- 6374 TUMOR DEVELOPMENT IN THE WALL OF CONGENITAL LUNG CYSTS. (Rus.) Babashayev, B. S. (Kazakh Inst. Clin. Exp. Surg., Kazakh SSR Min Pub Hlth, Alma-Ata, USSR) and S. A. Voronov. *Vop Onkol* 18(9):79-81, 1972.
- 6375 THE USE OF RNA LABELED IN VITRO WITH IODINE-125 IN MOLECULAR HYBRIDIZATION EXPERIMENTS. (E.) Getz, M. J. (U. Texas M. D. Anderson Hosp., Houston), L. C. Althernburg and G. F. Saunders. *Biochim Biophys Acta* 287(3):485-494, 1972.
- 6376 EARLY DETECTION OF DIGESTIVE TRACT CARCINOMAS. (Ger.) Classen, M. (Erlangen, W. Germany). *11th Meeting German Cancer Assoc Hannover (Sept):*99, 1971.
- 6377 CARCINOMA OF THE BREAST. (Ger.) Kindermann, G. (Erlangen, W. Germany). *11th Meeting German Cancer Assoc Hannover (Sept):*100-101, 1971.
- 6378 ANATOMICOPATHOLOGICAL PREAMBLES ON THE CLASSIFICATION AND HISTOLOGICAL EVALUATION OF PRIMARY BONE TUMORS. (Ger.) Uehlinger, E. (Zürich, Switzerland). *11th Meeting German Cancer Assoc Hannover (Sept):*86-87, 1971.
- 6379 SEQUENCE ANALYSIS OF NUCLEOLAR AND RIBOSOMAL 28S RNA FROM NOVIKOFF HEPATOMA AND RAT LIVER. (Ger.) Seeber, S. (Houston, Texas) and H. Busch. *11th Meeting German Cancer Assoc Hannover (Sept):*74-75, 1971.
- 6380 CHROMOSOMAL ANAOMALIES IN NEOPLASIA. (Ger.) Hossfeld, D. K. (Essen, W. Germany). *11th Meeting German Cancer Assoc Hannover (Sept):*71-72, 1971.
- 6381 THE EFFECT OF TUMOR METABOLITES ON THE ORGANISM DURING DIFFERENT GROWTH STAGES OF SOLID WALKER CARCINOMA 256 IN THE RAT. (Ger.) Ertl, N. (Heidelberg, W. Germany). *11th Meeting German Cancer Assoc Hannover (Sept):*68-69, 1971.
- 6382 THE EFFECT OF PREGNANCY ON THE COURSE OF CARCINOMA OF THE UTERINE CERVIX. (Ger.) Grupp, H.-J. (Berlin, W. Germany) and H. Lemtis. *11th Meeting German Cancer Assoc Hannover (Sept):*65-66, 1971.
- 6383 HISTOLOGY, CLINICAL STAGE, AND PROGNOSIS OF HODGKIN'S DISEASE. (Ger.) Merten, D. (Frieburg im Bresgau W. Germany), K. Musshoff, W. Oehlert, W. Reichardt, and P. Kalkoff. *11th Meeting German Cancer Assoc Hannover (Sept):*51-52, 1971.
- 6384 EXPERIMENTAL STUDIES OF THE SUBCELLULAR DISTRIBUTION AND BINDING OF GALLIUM-67. (Ger.) Deckner, K. (Essen, W. Germany), G. Becker, U. Langowski, H. Schwering and C. G. Schmidt. *11th Meeting German Cancer Assoc Hannover (Sept):*94-95, 1971.

85 HODGKIN'S DISEASE OF THE LUNG. (Ger.)
Morawetz, F. (Vienna, Austria). 11th
Meeting German Cancer Assoc Hannover (Sept):54-56,
1971.

86 LYMPHOGRANULOMATOSIS OF THE SKELETON.
(Ger.) Firusian, N. (Essen W. Germany)
and O. Wetter. 11th Meeting German Cancer Assoc
Hannover (Sept):56-57, 1971.

87 LYMPHOGRANULOMATOSIS AND PREGNANCY. (Ger.)
Verhagen, A. (Plettenberg, W. Germany).
11th Meeting German Cancer Assoc Hannover (Sept):
58-59, 1971.

88 NON-SPECIFIC MESENCHYMAL REACTION AND
PARENCHYMAL DAMAGE OF THE LIVER IN
PATIENTS WITH HODGKIN'S DISEASE. (Ger.) Oehlert,
(Freiburg im Breisgau, W. Germany) and W.
Schler. 11th Meeting German Cancer Assoc
Hannover (Sept):50-51, 1971.

89 INTERCELLULAR COMMUNICATION IN NORMAL AND
MALIGNANT CELLS. (Ger.) Hülser, D. F.
(Tübingen, W. Germany) and M. F. Rajewsky. 11th
Meeting German Cancer Assoc Hannover (Sept):22-23,
1971.

90 HAMSTER MELANOMA RNA-POLYMERASES AND DRUG-
INDUCED EFFECTS. (Ger.) Balda, B.-R.
(Munich, W. Germany) and G. D. Birkmayer. 11th
Meeting German Cancer Assoc Hannover (Sept):23-24,
1971.

91 THE ACTION OF PROFLAVIN ON THE TUMOR-
SPECIFIC PROTEINS OF HAMSTER MELANOMA.
(Ger.) Birkmayer, G. D. (Munich, W. Germany)
and B.-R. Balda. 11th Meeting German Cancer Assoc
Hannover (Sept):24-26, 1971.

92 THE PATHOLOGICAL FEATURES OF LYMPHOGRANU-
LOMATOSIS. (Ger.) Lukes, R. J. (Los
Angeles, USA). 11th Meeting German Cancer Assoc
Hannover (Sept):43-44, 1971.

93 HISTOLOGICAL COURSE OF HODGKIN'S DISEASE
AND ITS RELATIONSHIP TO LUKES CLASSIFICA-
TION. (Ger.) Georgii, A. (Hannover, W. Germany).
11th Meeting German Cancer Assoc Hannover (Sept):
44-45, 1971.

94 EARLY DETECTION OF CARCINOMA OF THE PROS-
TATE. (Ger.) Klosterhalfen, H.
(Hamburg, W. Germany). 11th Meeting German Cancer
Assoc Hannover (Sept):101-102, 1971.

95 THE EFFECT OF HYPERTHERMIA ON THE INCOR-
PORATION OF NUCLEIC ACID PRECURSORS IN

VITRO IN MALIGNANT TUMORS, NORMAL TISSUES, AND FAST
PROLIFERATING TISSUES. (Ger.) Wüst, G. P.
(Münster, W. Germany), K. Norpoth and U. Witting.
11th Meeting German Cancer Assoc Hannover (Sept):
113-114, 1971.

6396 TYPICAL CANCER SITES IN WOMEN. CANCER OF
THE BREAST AND CANCER OF THE LOWER
ABDOMEN. (Ger.) Stoll, P. (Mannheim, W. Germany).
11th Meeting German Cancer Assoc Hannover (Sept):
102-103, 1971.

6397 EARLY DETECTION OF BRONCHIAL CARCINOMA.
(Ger.) Trendelenburg, F. (Homburg, W.
Germany). 11th Meeting German Cancer Assoc
Hannover (Sept):103-106, 1971.

6398 THERMOGRAPHIC EARLY DIAGNOSIS OF BREAST
CARCINOMA. (Ger.) Otto, R. (Lausanne,
Switzerland) and C. Hessler. 11th Meeting German
Cancer Assoc Hannover (Sept):106-107, 1971.

6399 THE DIAGNOSTIC VALUE OF THE RELATIVE BLOOD
IRRIGATION FOR EARLY DETECTION OF BREAST
CARCINOMA BY MEANS OF THE INFRARED-THERMOGRAM.
(Ger.) Haas, R. (Giessen, W. Germany), D.
Rossmeis; R. Kraus and E. Tahalele. 11th Meeting
German Cancer Assoc Hannover (Sept):107-109,
1971.

6400 KINETICS OF CALCIUM METABOLISM IN MALIG-
NANT BONE TUMORS AND BONE TUMOR METASTASES.
(Ger.) Sack, H. (Essen, W. Germany). 11th Meeting
German Cancer Assoc Hannover (Sept):91-93, 1971.

PREFACE

Carcinogenesis Abstracts is a publication of the National Cancer Institute. The journal serves as a vehicle through which current documentation of carcinogenesis research highlights are compiled, condensed, and disseminated on a regular basis. It represents an integral part of the Institute's program of fostering and supporting coordinated research into cancer etiology. Issues of *Carcinogenesis Abstracts* normally contain three-hundred-fifty abstracts and three-hundred-fifty citations (unaccompanied by corresponding abstracts). Abstracts and citations refer to the current scientific literature that describes the most significant carcinogenesis research carried on at the National Cancer Institute, other governmental agencies, and private institutions. *Carcinogenesis Abstracts* is intended to be a highly useful current awareness tool for scientists engaged in carcinogenesis research or related areas. The great number and diversity of publications relevant to carcinogenesis make imperative the availability of this service to investigators whose work requires that they keep abreast with current developments in the field.

Carcinogenesis Abstracts is normally published monthly. Volume X covers the scientific literature published from July 1971 through Dec 1972. A cumulative subject and author index for Volume X will be published shortly after the final regular issue. This journal is available free of charge to libraries and to individuals who have a professional interest in carcinogenesis. Requests for *Carcinogenesis Abstracts* from qualified individuals should include statements of their relationship to carcinogenesis research. All correspondence should be addressed as follows.

Carcinogenesis Abstracts
Etiology Area
National Cancer Institute
National Institutes of Health
Bethesda, Maryland 20014

Use of Funds for Printing this publication
approved by the Director of the Bureau of
the Budget on July 25, 1967.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotrophic hormone	mg	milligram(s)
ADP	adenosine diphosphate	min	minute(s)
AMP	adenosine monophosphate	ml	milliliter(s)
ATP	adenosine triphosphate	mm	millimeter(s)
C	degrees centigrade	MTD	maximum tolerated dose
cm	centimeter(s)	ng	nanogram (10^{-9})
CNS	central nervous system	pg	picogram (10^{-12})
cpm	counts per minute	p.o.	orally
DNA	deoxyribonucleic acid	ppm	parts per million
e.g.	for example	r	Roentgen
g	gram(s)	RBC	red blood cells (erythrocytes), red blood count
µg	microgram(s)	resp.	respectively
hr	hour(s)	Rev.	review (only in citations)
i.m.	intramuscular	RNA	ribonucleic acid
i.p.	intraperitoneal	s.c.	subcutaneous
IU	international unit(s)	sec	second(s)
i.v.	intravenous	U	unit(s)
kg	kilogram(s)	UV	ultraviolet
LD ₅₀	median lethal dose(s)	WBC	white blood cells (leukocytes), white blood count
m	meter(s)	wk	week(s)
M	molar	wt	weight
mEq	milliequivalent(s)	yr	year(s)
mM	millimolar		
µM	micromolar		
mC, µC	milli-, microcurie(s)
